What is a Microgrid?

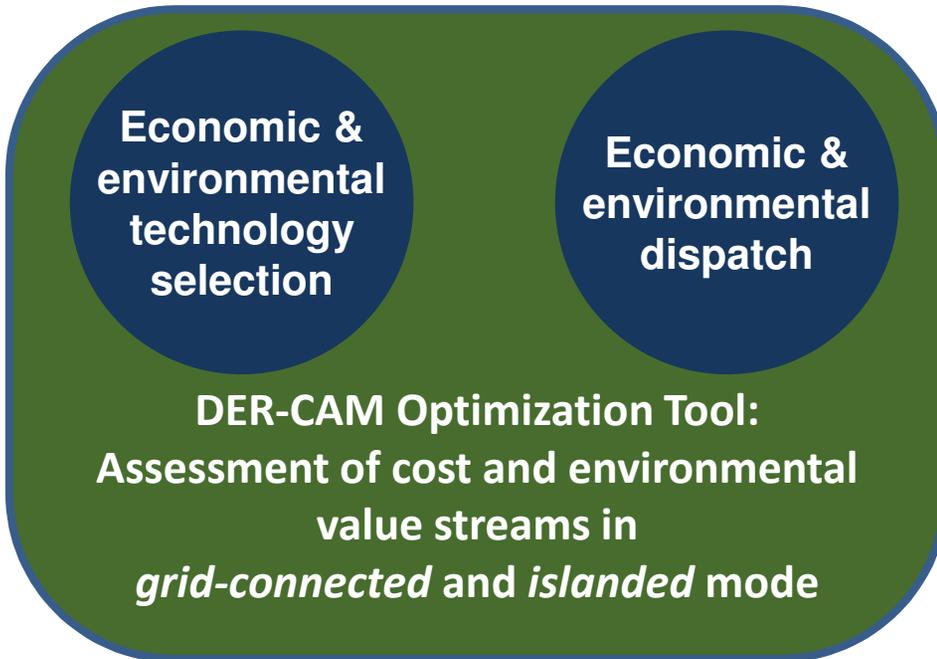

A *microgrid* is a

- group of interconnected loads and distributed energy resources
- acts as a single controllable entity with respect to the grid
- can connect/disconnect from the grid
- operates in both grid-connected or island mode

(Microgrid Exchange Group, October 2010)

Distributed Energy Resources Customer Adoption Model (DER-CAM)

- is a deterministic and stochastic Mixed Integer Linear Program (MILP), written in the General Algebraic Modeling System (GAMS®)
- started as a building CHP optimization tool 13 years ago
- supported by the U.S. DOE, OE, DoD, CEC, private industry
- two main objective functions:
 - cost minimization
 - CO₂ minimization
- other objectives are possible, as well as multi-objective subject to microgrid/building constraints and energy balance
- produces optimal investment and dispatch results for biogas/diesel/natural gas CHP, fuel cells, ICE, micro-turbines, gas-turbines; PV, solar thermal, hot and cold water storage, batteries, heat pumps, absorption chiller, EV, passive measures (insulation, window changes, etc..)

DER-CAM

DECISION SUPPORT TOOL FOR
DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

What is DER-CAM?

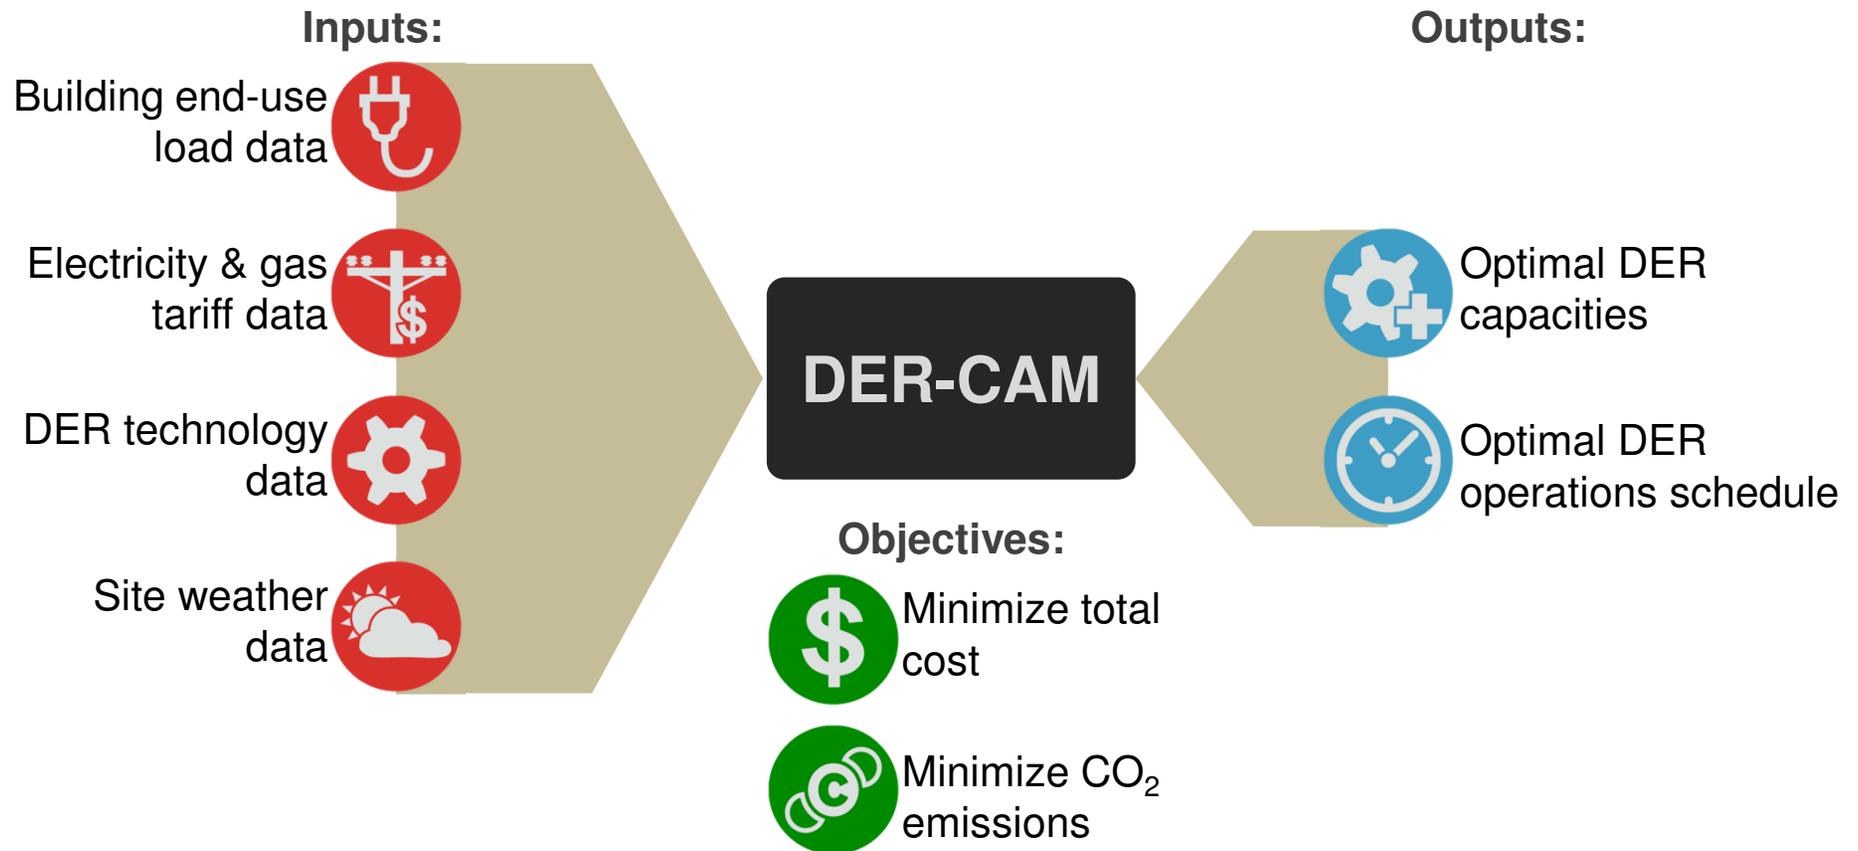

- optimizes heating, cooling, electricity, and fuel loads (as natural gas)
- can consider real microgrid conditions as islanding and critical loads
- 17 specific versions exist (<http://building-microgrid.lbl.gov/sites/all/files/projects/DER-CAM-Feature-List.pdf>)
- commercialization (*web clients*) and predictive controller work under way
- 550 DER-CAM *web clients* to date (English and Chinese version)

DER-CAM

DECISION SUPPORT TOOL FOR
DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

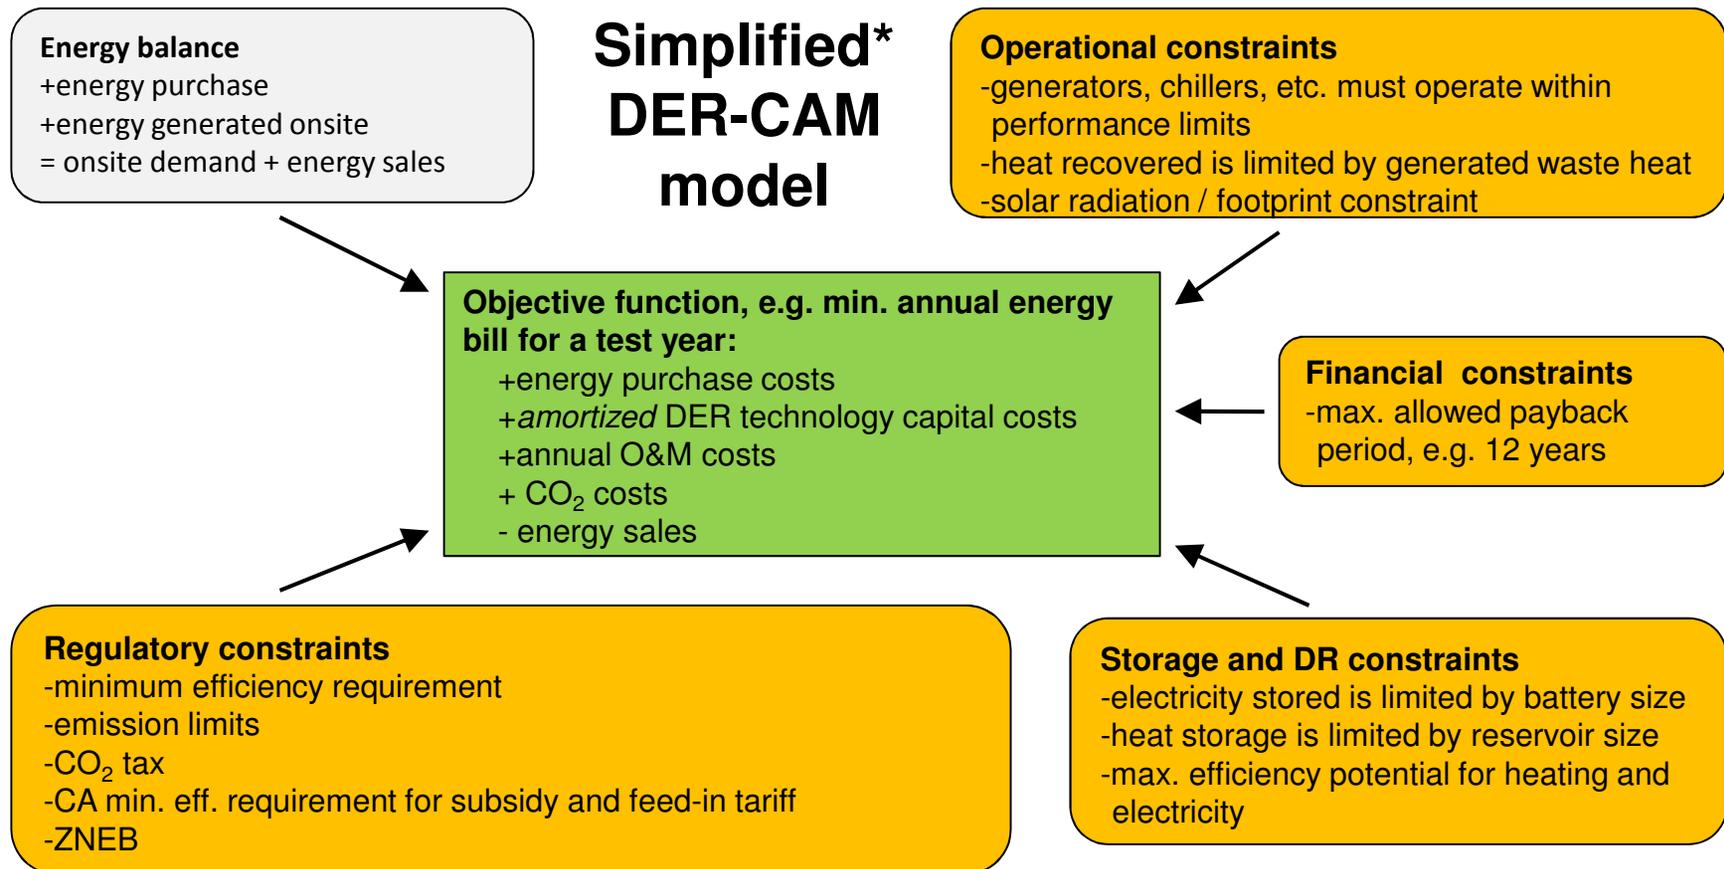

- **Investment & Planning:** determines optimal equipment combination and operation based on *historic* load data, weather, and tariffs
- **Operations:** determines optimal week-ahead scheduling for installed equipment and *forecasted* loads, weather and tariffs

Our Partners and DER-CAM Licensees

Our Partners

Features and Applications

- remote access
- microgrid capabilities and resilience at Fort Hunter Liggett
- optimization of cooling equipment at UNM
- battery scheduling at Santa Rita Jail

-----Backup-----

- passive measures
- critical loads
- stepwise approximation of non-linear efficiency curves
- tracking of thermal storage temperature
- wind in DER-CAM
- electrochromic windows
- multi-year optimization (decision support)
- EV modelling
- CA CHP study
- microgrid controller at Fort Hunter Liggett

Feature

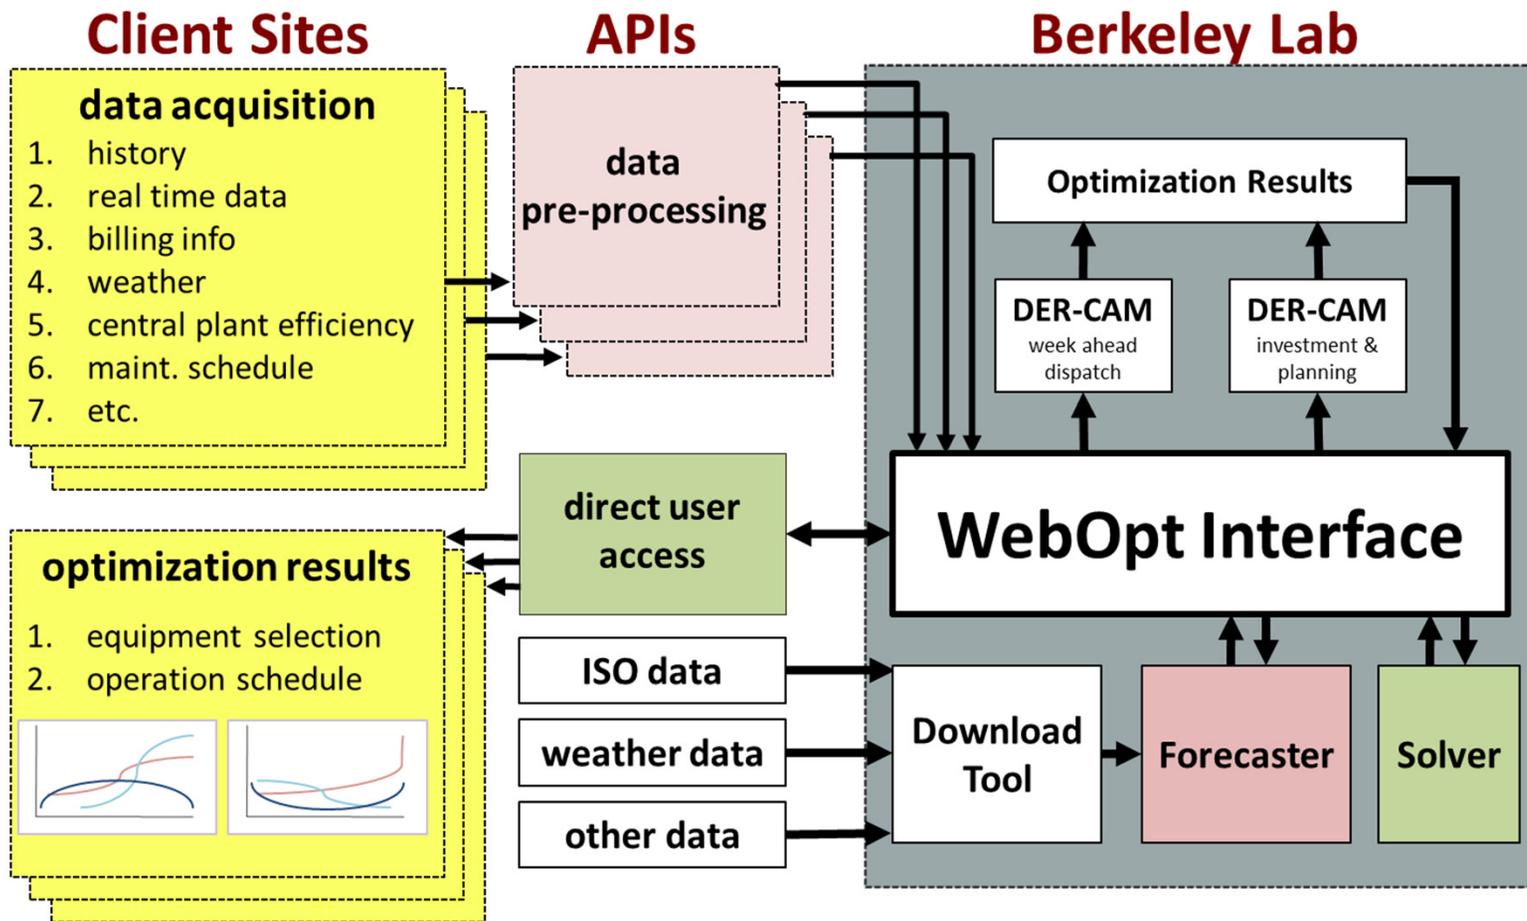

Remote Access to DER-CAM

DER-CAM

DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

Access to DER-CAM via SaaS

Simplified DER-CAM Web-Service for Investment/Planning DER-CAM

The screenshot displays the DER-CAM Web-Service interface. The browser address bar shows <https://microgrids2.lbl.gov/>. The page title is "Distributed Energy Resources (DER) Web Optimization Service (WebOpt)".

The main navigation bar includes: Overview/Optimization Settings, Load Profiles, Utility Tariffs, Technologies, Demand Response, Solar Radiation, Marginal CO2 Macrogrid, Results, and WebOpt Guide.

A "Run optimization" button with a "GO" label is visible on the left. Below it, a message states: "This Tab shows the results of the optimization. Please scroll down to view the pictures."

The "Results" tab is active, showing a "Multi-objective frontier" plot. The plot displays "Annual energy costs (k\$)" on the y-axis (ranging from 391.88 to 691.88) and "Annual CO2 emissions (metric ton)" on the x-axis (ranging from 946.72 to 1646.72). A tooltip for "F point 6" provides the following data:

- Total Annual Energy Costs, including annualized investment costs (k\$): 659
- Annual CO2 Emissions (Grand Total) (tCO2): 976
- Installed Capacity, discrete technologies as CHP/DG (kW): 250
- Installed Battery Capacity (kWh): 626
- Installed Capacity Photovoltaic (kW), peak power under test conditions: 459
- Size of Photovoltaic (m²): 3000
- Installed Capacity Ground Source Heat Pump (kWelec_demand, kWheat, kWcooling, U.S. RT): 171, 855, 855, 243

A "WebOpt Manual" window is open, displaying text about advanced input options. The manual text includes:

- useful if the user wants to assess scenarios with higher costs than the base case/do-nothing, e.g. CO2 minimization runs.
- Show advanced input options:** If checked, Figure 9 will be displayed. The initial investment costs for all DER will be annualized using the specified *interest rate* and this annualized investment cost added to the energy bill. The *maximum allowed annual energy cost* is the maximum amount the user is willing to pay, and the *maximum pay-back period for the initial investment* is the maximum length of time required to recover the cost of an investment.

The manual window also shows input fields for:

- Interest rate for investments: 6 %
- Max. available space for PV system at site: 3000 m²
- Max. allowed annual energy costs (including annualized capital costs): 59 k\$
- Max. pay back period for investments: 12 years

Figure 9. Advanced Input options under Overview/Optimization settings

The *Maximum available space for PV system at site* specifies an upper boundary for PV and solar thermal system installation. The available space on the rooftop may be a good estimate of this figure.

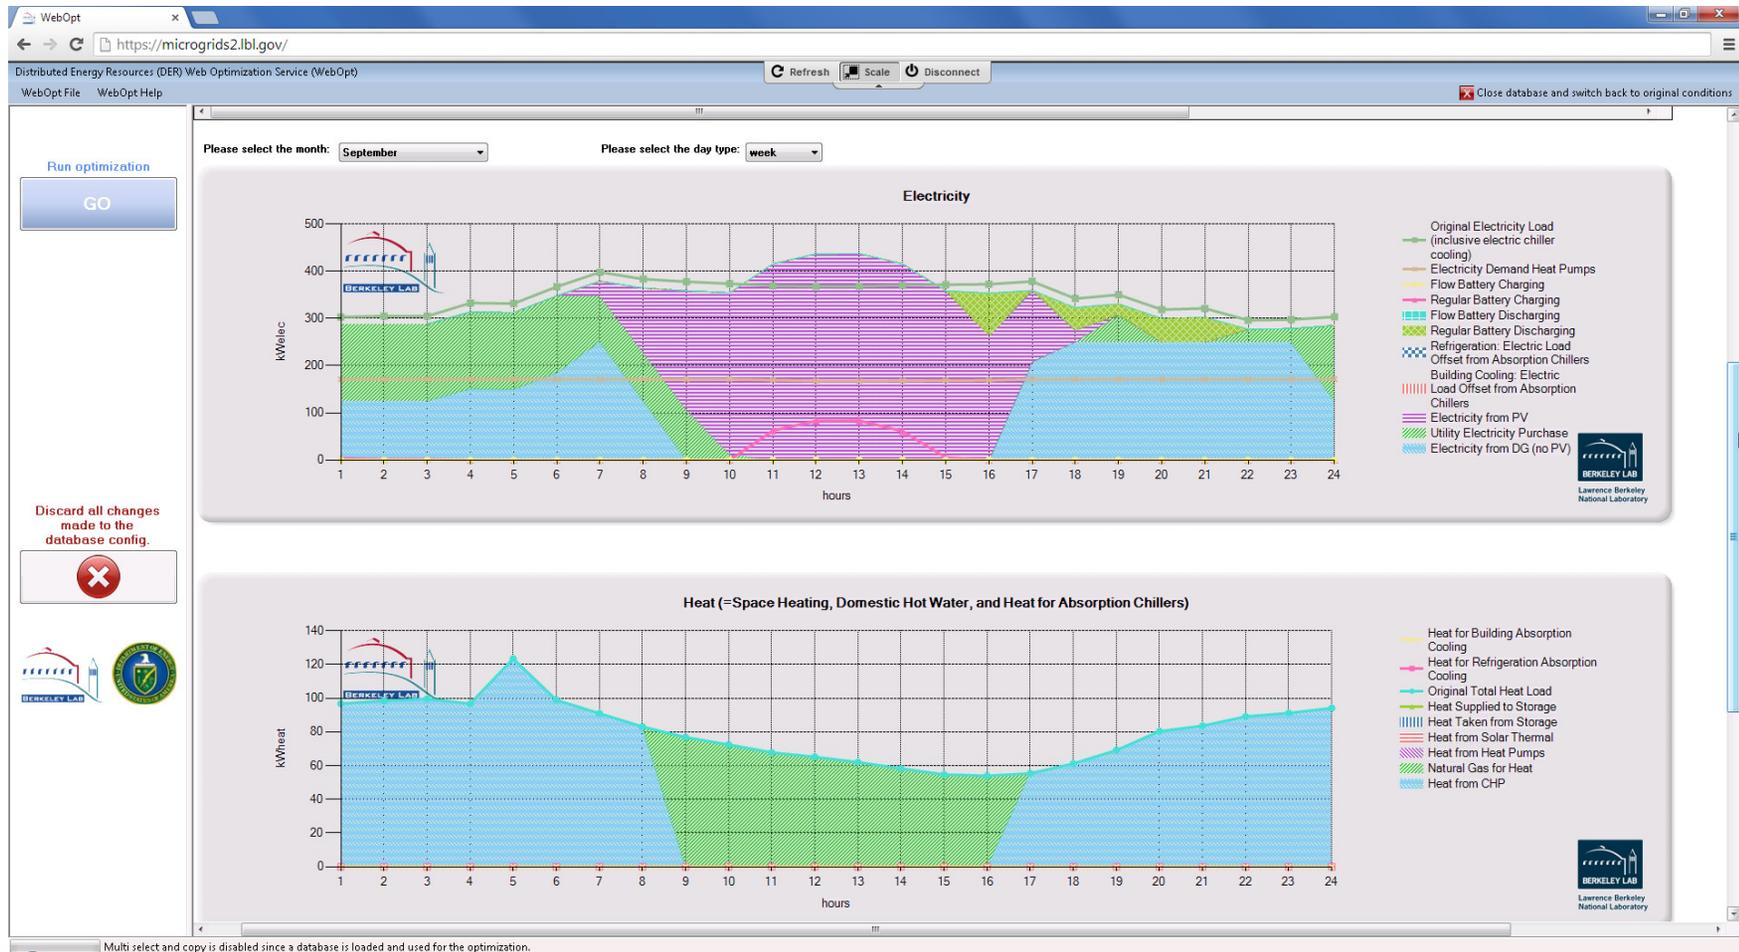

Optimization objective: The user can specify a cost minimization or CO2 minimizing objective as well as a **multi-objective** frontier with cost constraint, e.g., a combination of cost and CO2 minimization. In case of cost minimization, it is possible that the optimization will result in few or no installed DER, meaning that it is cheaper to not invest and only purchase from the utility.

At the bottom of the browser window, a status bar reads: "Multi select and copy is disabled since a database is loaded and used for the optimization."

Extended Load Profile Database

USA

AK AZ CA CO FL GA IL MD MN MT

Please select a state and city as well as vintage from the database on the left (click on the folder icon). The database is based on ASHRAE climate zones (see picture below). If you do not find a state and city in the database, select one from the same climate zone (e.g. use MD and Baltimore for NYC).

Note that load profiles in this database are normalized to 1 GWh of electricity and 1 GWh of natural gas load per annum. In other words, all DER-CAM electricity loads (electricity only, cooling, and refrigeration) are normalized to 1 GWh. Also, all DER-CAM natural gas loads (heating, domestic hot water, and natural gas only loads) are normalized to 1 GWh.

To model your building, just check your annual electricity and natural gas bill and enter the annual electricity and natural gas demand in the boxes below to scale the database load profiles to reflect your building.

[1 GWh - gigawatt hour = 1 000 000 kWh and 1 kWh = 3412.14 BTU, 1 Therm (US) = 100,000 BTU = 29.3 kWh]

Annual electric demand: 1 GWh

Annual natural gas demand: 1 GWh

Transferability: Online DER-CAM User Guide

The screenshot displays the WebOpt interface for DER-CAM. At the top, there is a navigation bar with tabs for Overview/Optimization Settings, Load Profiles, Utility Tariffs, Technologies, Demand Response, Solar Radiation, Marginal CO2 Macrogrid, Results, and WebOpt Guide. Below this is a 'Run optimization' button with a 'GO' label and a 'Discard all changes' button with a red 'X' icon. The main content area is titled 'WebOpt - the Free Web Optimization Version of DER-CAM' and features a central diagram of the 'MICROGRID' system. This diagram shows 'Distributed Energy Resources' (including Conventional, New Emerging, and Renewable Based technologies) interacting with 'Resources' (Utility, Fuel, Local Resources) and 'Energy Demand' (heating, cooling, electricity). The system is managed through 'Optimal Planning and Operations' across three phases: ANALYTICS, PLANNING, and OPERATIONS. To the right, there are several data visualization charts, including a 'Multi-objective' chart and an 'Electricity' chart showing power flow over time. Below the main diagram is a 'Work Flow' section with a sequence of steps: Define Investment / Planning Parameters, Input / Define Electric or Heating Loads, Input / Define Electric and Natural Gas Rates, Specify Energy Technology Parameters, Define Additional Demand Response Measures, Specify Solar Radiation, Specify Utility CO2 Emissions, and Analytics. A 'Go' button is placed between the last two steps. Logos for Berkeley Lab and the University of California are visible in the bottom left. A 'Manual' and 'Help' button are located in the bottom right.

Application

Microgrid Capabilities and Resiliency at Fort Hunter Liggett

DER-CAM

DECISION SUPPORT TOOL FOR
DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

Overview

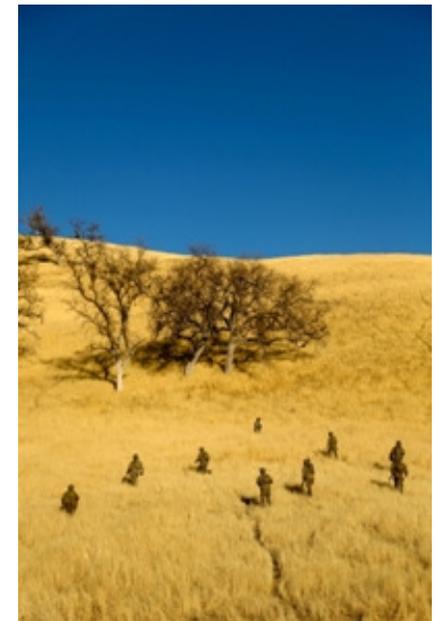

- Training facility for combat support and combat service support units of the Army Reserve
- Largest installation in the Army Reserve (> 165,000 acres)
- Existing DER: 2MW PV + 1MWh battery
- Future: Large (>1MW) PV and battery system to be installed by TriTechnic together with Siemens and the U.S. Army

Objective

Enable Microgrid capabilities and install DER-CAM supervisory controller

DER-CAM Contribution

- Use DER-CAM to gauge optimal capacity of DER
 - Consider additional PV and storage
 - Backup generation
 - Short vs. long duration blackouts
 - Optimal DER capacity

source: <http://www.liggett.army.mil/>

DER-CAM

DECISION SUPPORT TOOL FOR
DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

Objective: Use DER-CAM to perform a quick assessment on optimal DER at FHL to enable microgrid capabilities. Focus on resilience against natural disasters.

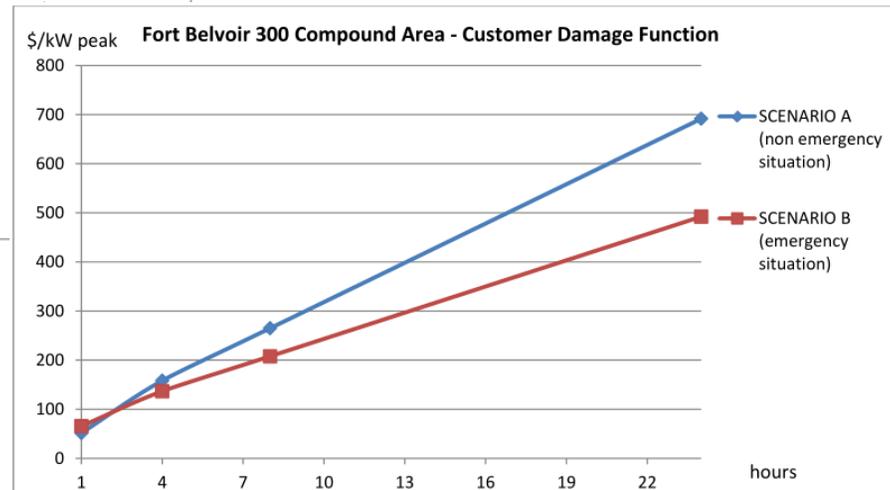

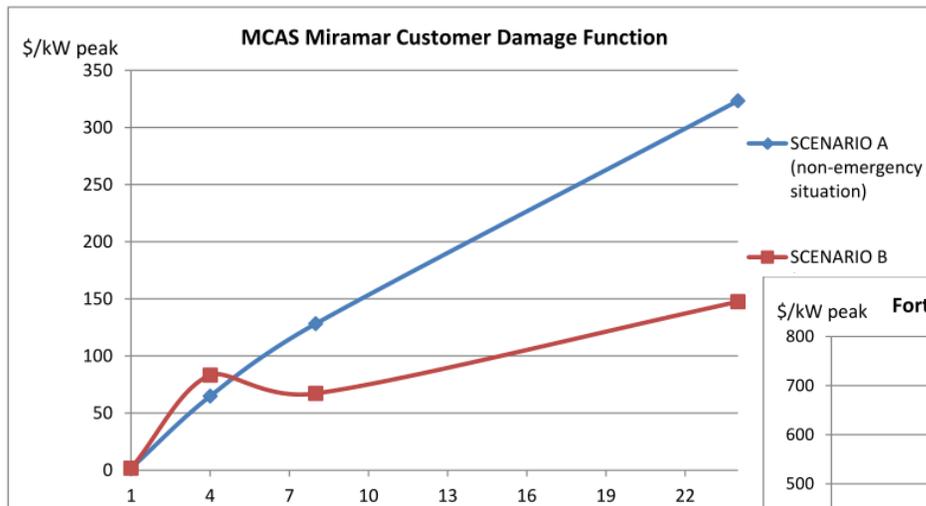

- Blackout cases: none, 3 h, 24 h, 7 days
- Standard DER-CAM assessment (no blackouts):
 - Existing DER
 - Existing DER + additional PV and storage
 - Existing DER + additional DER (full DER-CAM technology range)
- DER-CAM assessment considering blackouts:
 - Existing DER
 - Existing DER + additional PV and storage
 - Existing DER + Diesel backup generators
 - Existing DER + additional PV, batteries and diesel backup generators
 - Existing DER + additional DER (full DER-CAM technology range)

Load prioritizations: 10% Critical loads; 20% Low Priority; 70% Medium priority

Fort Hunter Liggett – Customer Damage Function (CDF)

Customer Damage Function is used to estimate outage costs as a function of the outage duration.

*Value of Electrical Energy Security (VEES) ~ Outage Duration * \$/kW peak * Peak Demand*

Source:
Valuing Energy Security: Customer Damage Function Methodology
and Case Studies at DoD Installations, NREL

Standard DER-CAM assessment - no blackouts

Key Results*)

	BAU/Actual	Additional PV + Storage	All possible DER in DER-CAM
Annual Total Costs, million USD	3.035	2.948	2.701
Annual CO ₂ emissions, ton	4967	4161	4454
Photovoltaic, kW	2000	3032	2069
Electric Storage, kWh	1000	4141	1251
ICE, kW	-	-	2000
CHP: ICE + HX, kW	-	-	500
Absorption Chiller, kW	-	-	2828
Solar Thermal, kW	-	-	784

- Allowing additional PV and storage shows that the optimal investment capacity is higher, which is in accordance with the existing expansion plans of FHL
- Allowing other DER shows potential to reduce energy costs by up to 11% and CO₂ reductions by 10%

*) Sales are not part of this analysis

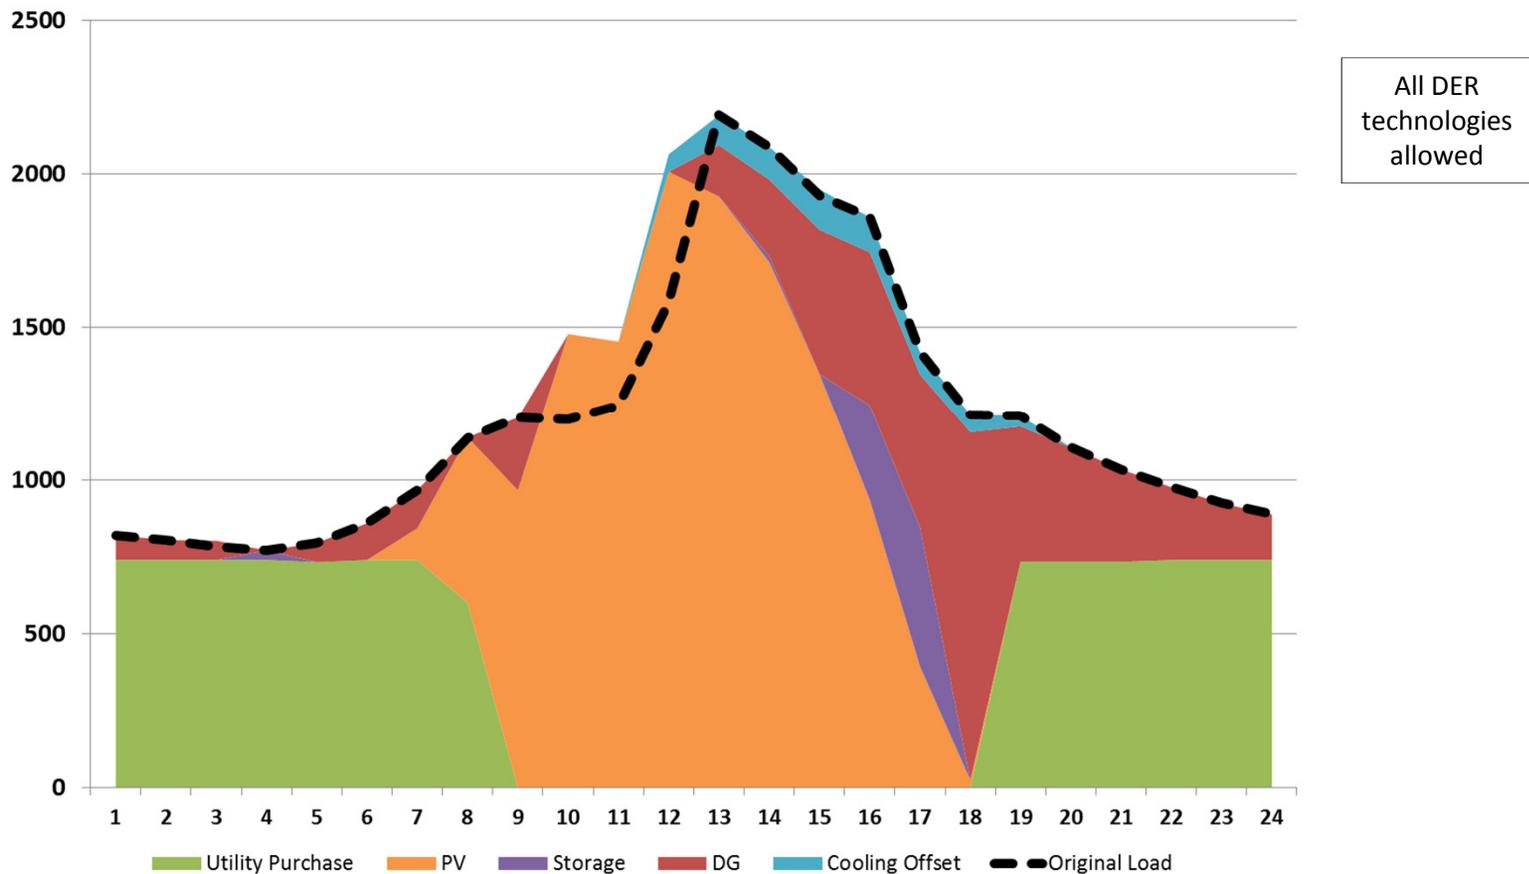

DER-CAM

DECISION SUPPORT TOOL FOR
DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

Standard DER-CAM assessment - no blackouts

Dispatch - October Week Day

PV generation enables frequent voluntary islanding (no energy purchase during the day)

Fort Hunter Liggett – DER-CAM assessment – with 3h blackout

Key Results*)

(Costs in million USD)	Existing PV and Storage	Existing PV, Storage + Diesel Backup	Additional PV and Storage	Additional PV, Storage and Diesel Backup	All DER
TOTAL COSTS	3.050	3.043	2.948	2.948	2.701
Electricity Costs	2.218	2.218	1.703	1.692	1.147
Fuel Costs	0.320	0.320	0.320	0.320	0.475
Annualized Capital Costs	0.491	0.493	0.915	0.926	0.974
O&M Costs	0.001	0.001	0.001	0.001	0.035
CDF Costs	0.015	0.005	-	-	-
Annual CO ₂ , ton	4966	4967	4177	4161	4455
<i>Installed capacity</i>					
Photovoltaic, kW	2000	2000	3079	3032	2068
Electric Storage, kWh	1000	1000	3845	4141	1251
Diesel Backup, kW	-	200	-	-	-
ICE, kW	-	-	-	-	2000
ICE HX, kW	-	-	-	-	500
Absorption Chiller, kW	-	-	-	-	2828
Solar Thermal, kW	-	-	-	-	783

- 3h blackout has little to no effect on results
- Existing capacity can be dispatched to meet all electric loads during short duration blackouts (some backup generators already exist at FHL)

*) Sales are not part of this analysis

DER-CAM

DECISION SUPPORT TOOL FOR
DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

Fort Hunter Liggett – DER-CAM assessment - 24h blackout

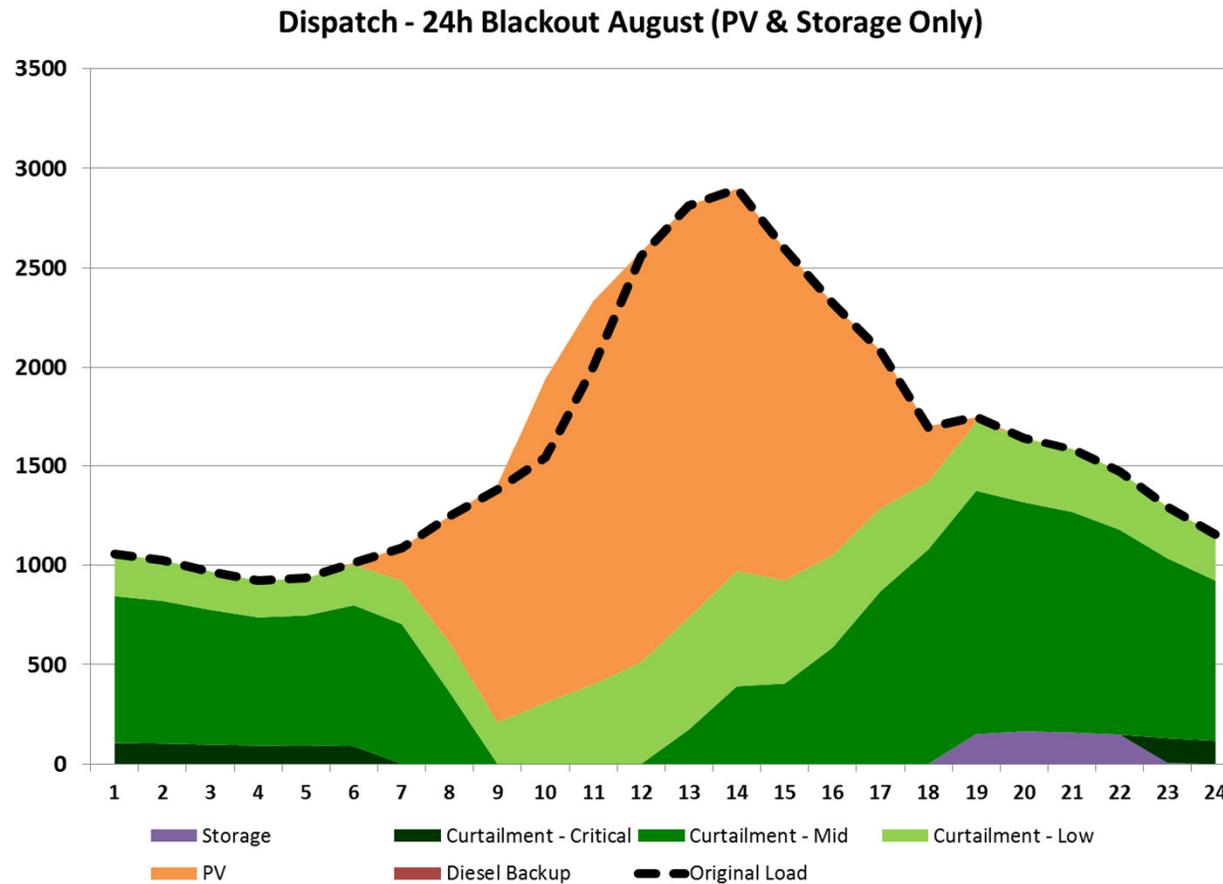

Key Results*)

(Costs in million USD)	Existing PV and Storage	Existing PV, Storage + Diesel Backup	Additional PV and Storage	Additional PV, Storage and Diesel Backup	All DER
TOTAL COSTS	5.363	3.068	3.655	2.976	2.702
Electricity Costs	2.216	2.216	0.785	1.661	1.145
Fuel Costs	0.320	0.326	0.320	0.324	0.477
Annualized Capital Costs	0.491	0.510	2.475	0.971	0.976
O&M Costs	0.001	0.001	0.001	0.001	0.036
CDF Costs	2.330	0.009	0.059	0.010	0.000
Annual CO ₂ , ton	4955	4973	2132	4119	4444
<i>Installed Capacity</i>					
Photovoltaic, kW	2000	2000	4936	3106	2077
Electric Storage, kWh	1000	1000	20709	4374	1250
Diesel Backup, kW	-	1400	-	1000	-
ICE, kW	-	-	-	-	2000
ICE HX, kW	-	-	-	-	500
Absorption Chiller, kW	-	-	-	-	2807
Solar Thermal, kW	-	-	-	-	801

- Results show that additional PV and storage, in addition to backup generation, will allow FHL to survive 24h outages without any major service disruption at low costs – diesel consumption roughly 1250 gallons for 24h
- When considering all DER options, the optimal investment solution allows enough flexibility to maintain operation during 24h outages and lowest costs

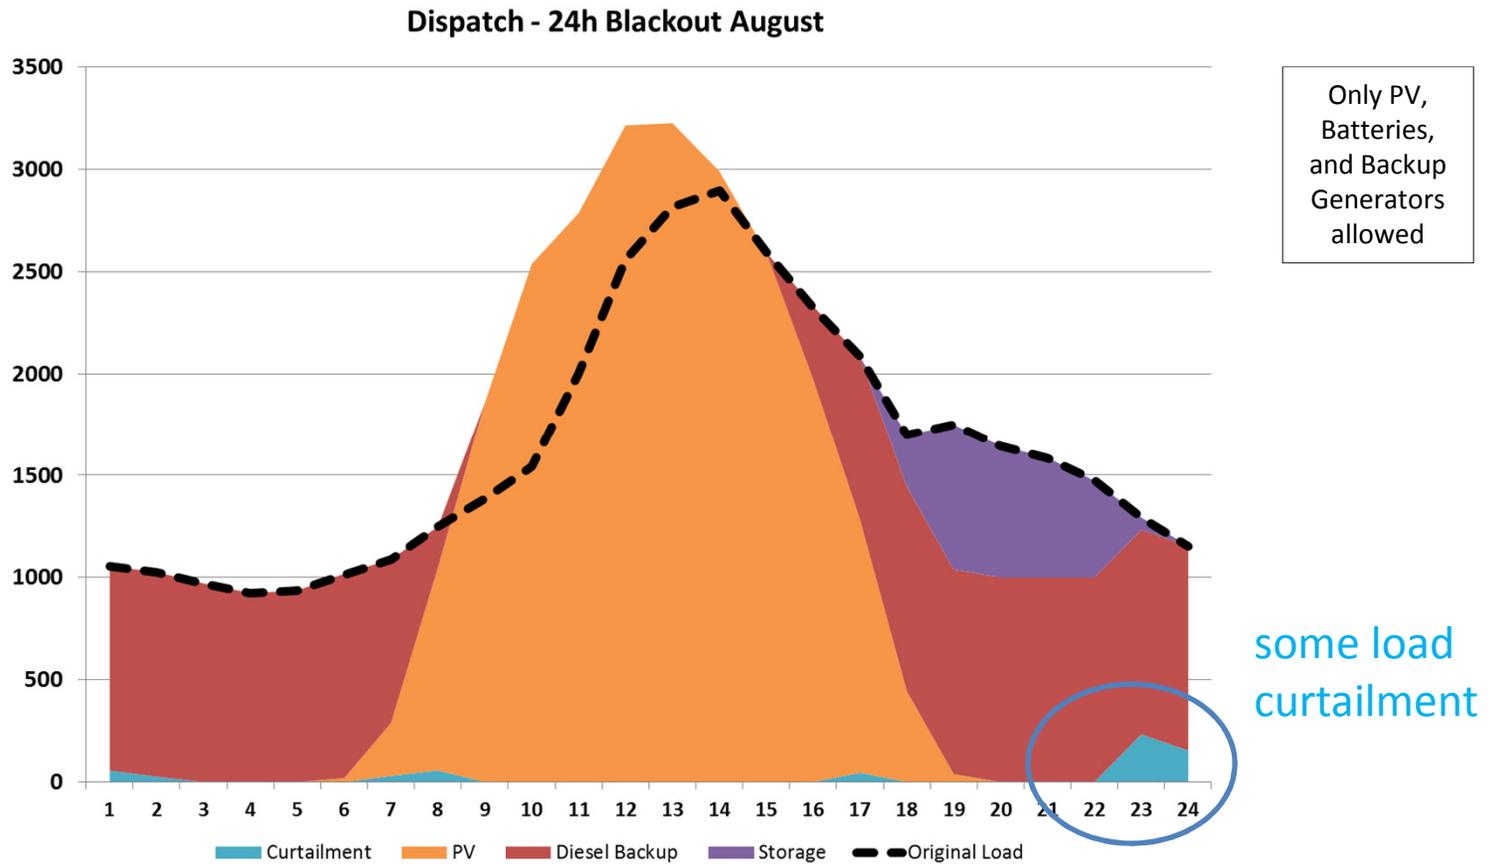

*) Sales are not part of this analysis

24h blackouts, only PV and storage

With the current PV and storage capacity alone, FHL would have severe curtailments in the event of a 24h outage, and would not be able to supply all loads

24h blackouts with PV, storage, and diesel backup generators

Planned expansion of PV and Storage, together with diesel backup generators will allow increased resilience at FHL

DER-CAM assessment – 7 day blackout

- Extremely high costs in prolonged outages with current resources (with existing equipment 24 millionUSD, all DER allowed only 3 millionUSD)
- Additional backup capacity increases significantly (up to 8 MW)
- Considering the capacity of DER to be implemented at FHL, the ability to maintain operation during prolonged blackout periods relies only on the size of fuel storage (fuel storage sizing) – consumption during blackouts approx. 3300 gallon LNG (12 500 liter)

Application

Cooling at the University of New Mexico

DER-CAM

DECISION SUPPORT TOOL FOR
DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

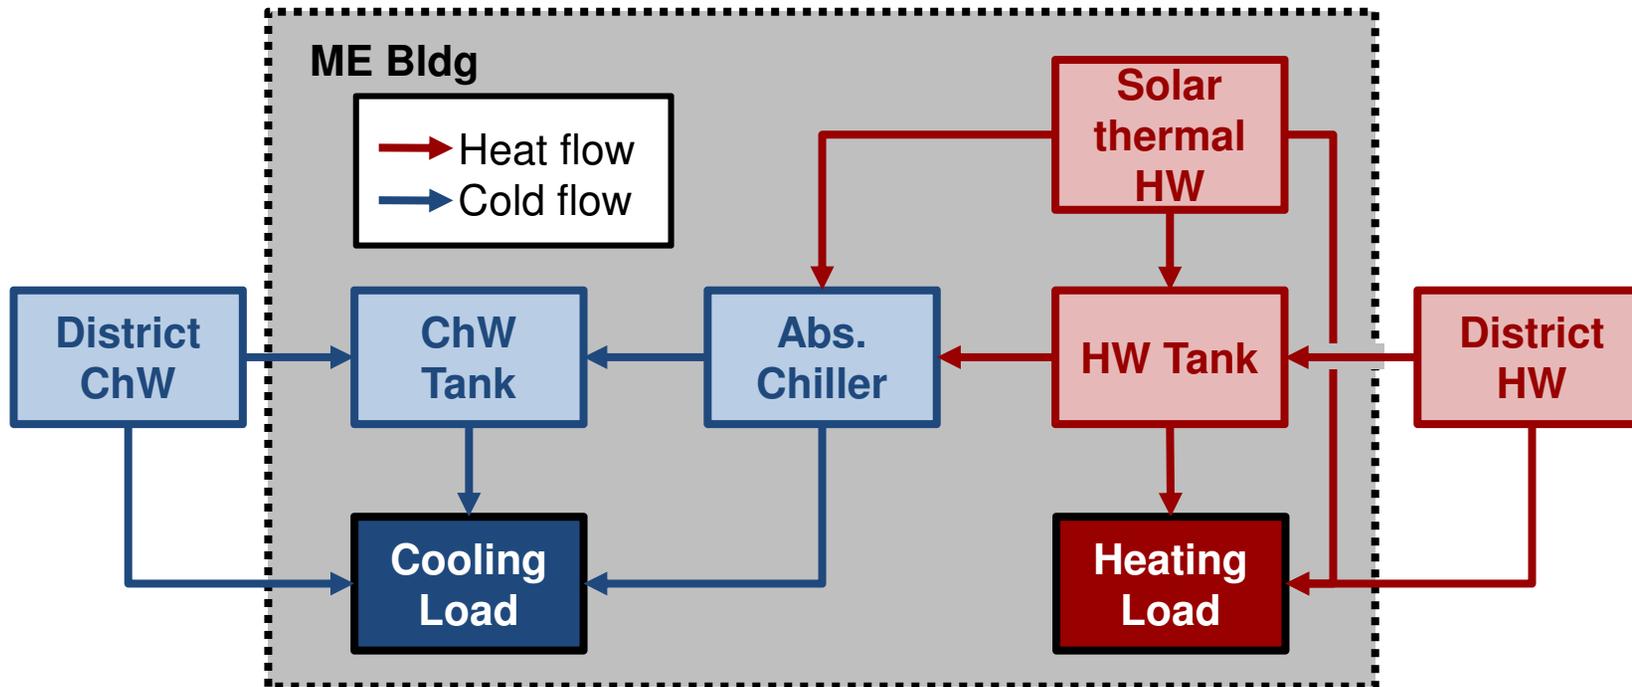

objectives:

- generate optimized scheduling of cooling equipment with Operations DER-CAM
 - solar thermal collection
 - hot water storage
 - chilled water storage
 - absorption chiller
- deliver results daily via automated interface to UNM building control system (delta controller)

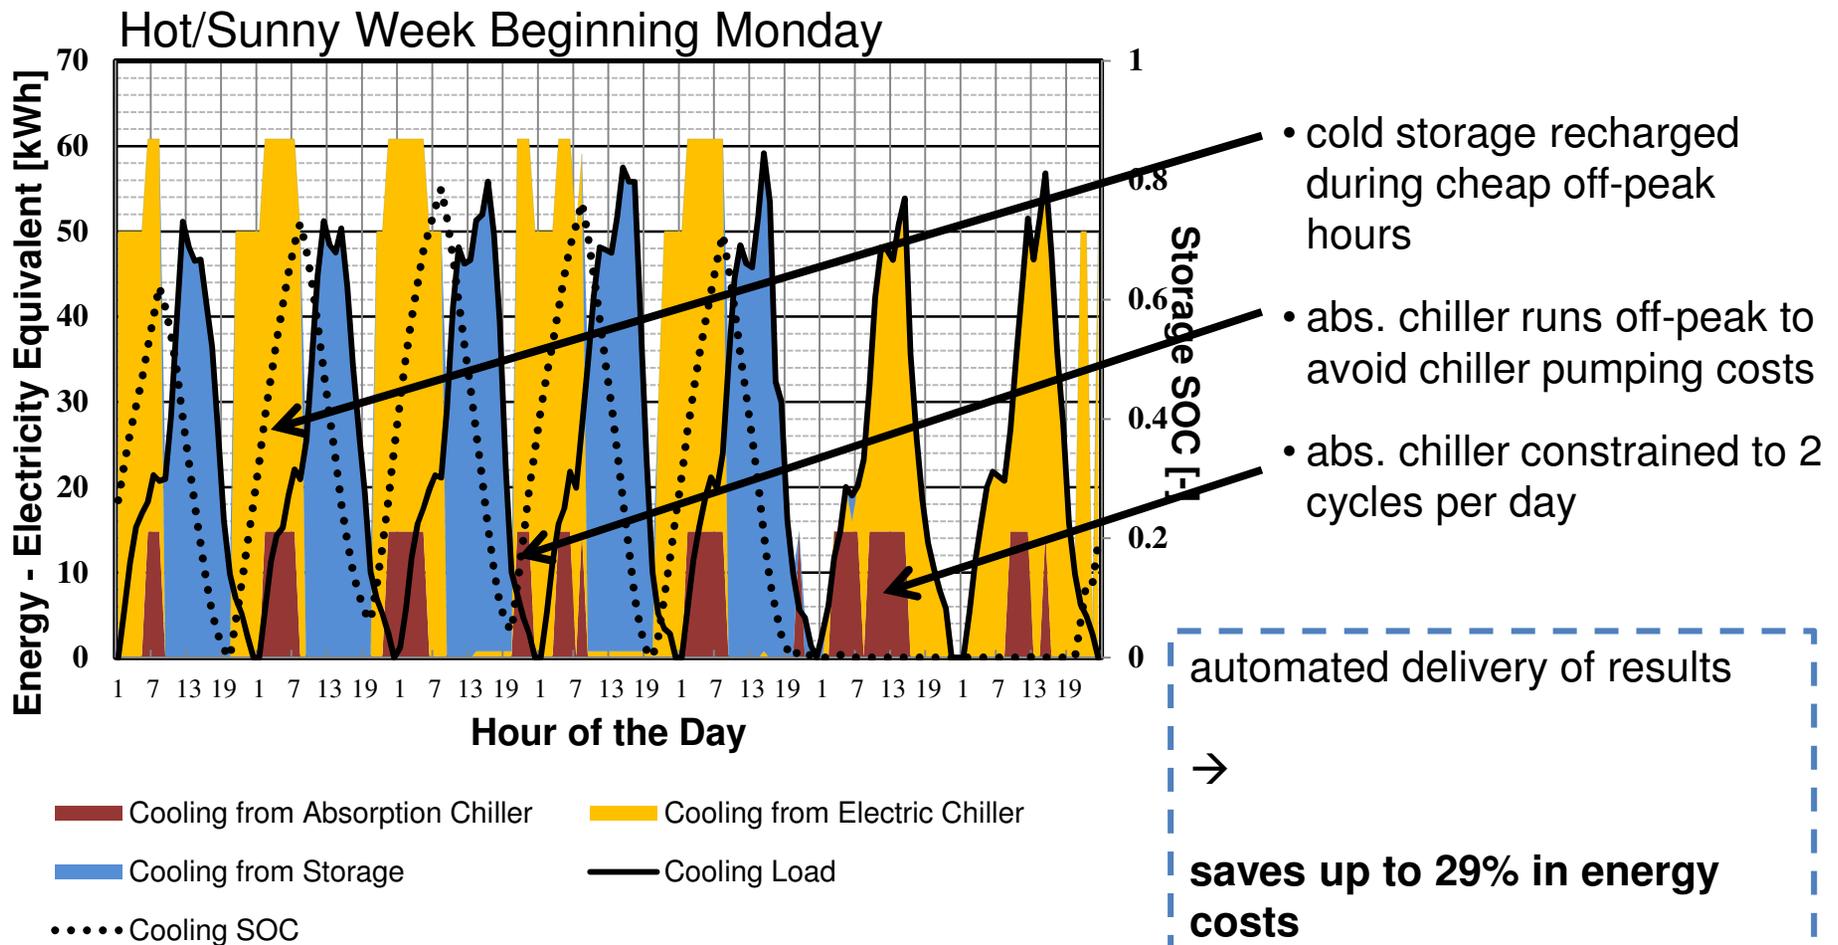

UNM Test Equipment/Configuration

equipment capacities:

- solar thermal: 170 kW peak rating
 - absorption chiller: 70 kW
 - chilled water storage: 3800 kWh
 - hot water storage: 300 kWh (9000 gallons)
- (all values thermal)

Application

Battery Scheduling at the Santa Rita Jail

DR and Battery at Santa Rita Jail (SRJ)

objectives:

- deliver optimized week-ahead scheduling of onsite electric storage with Operations DER-CAM
- determine potential reduction in utility feeder peak demand through *strategic battery dispatch*

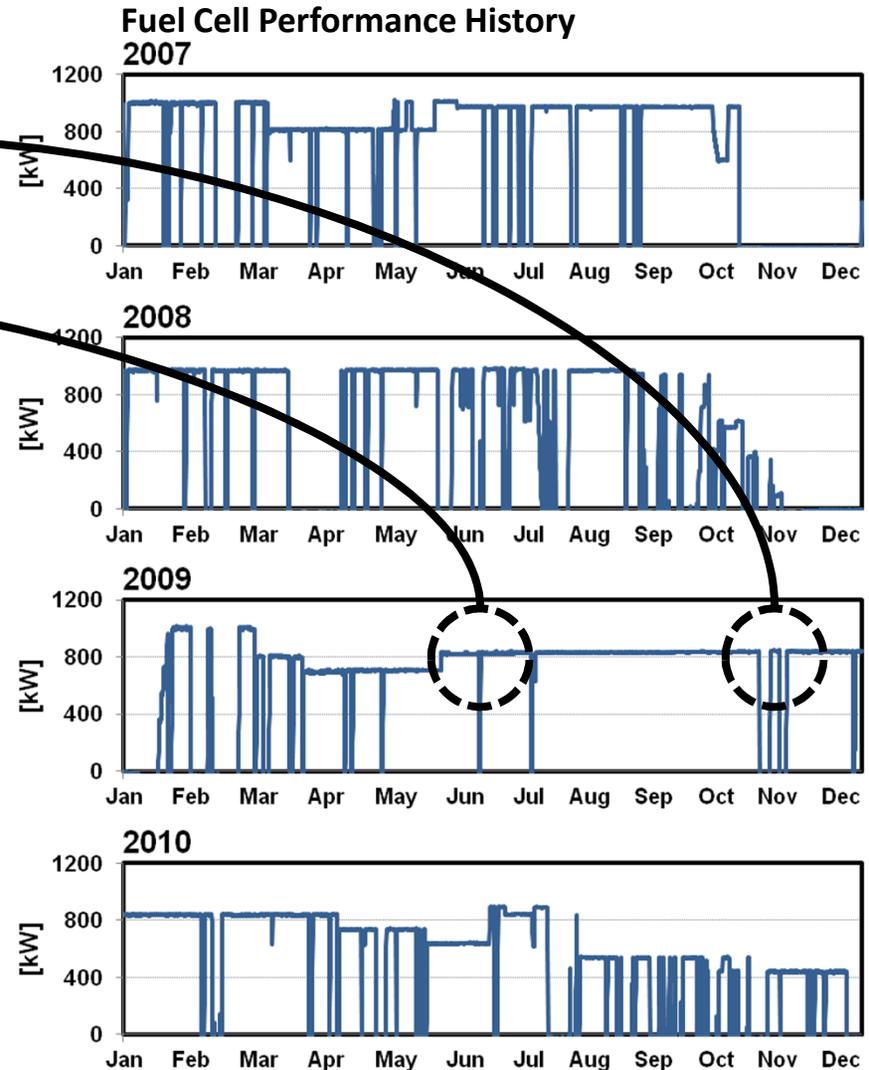

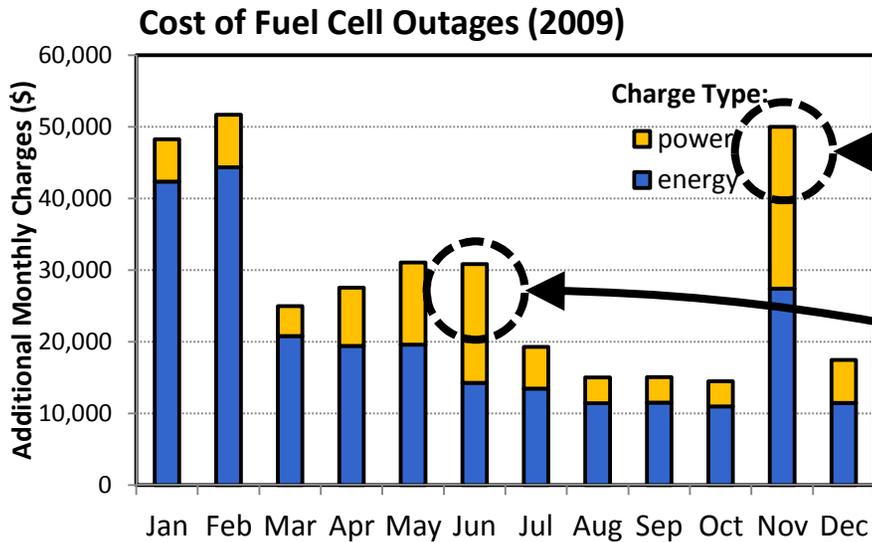

- 3 MW peak load facility
- CERTS microgrid functionality

DER On-site:

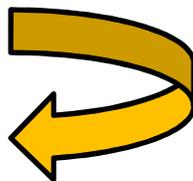

- photovoltaic: 1.2 MW peak
- fuel cell: 1 MW molten carbonate
- electric storage: 2 MW 2MWh Li-ion

Problems with Generation

- fuel cell experiences frequent outages
- even short outages can have significant economic impacts, by setting monthly power demand charges
- How can this be avoided?

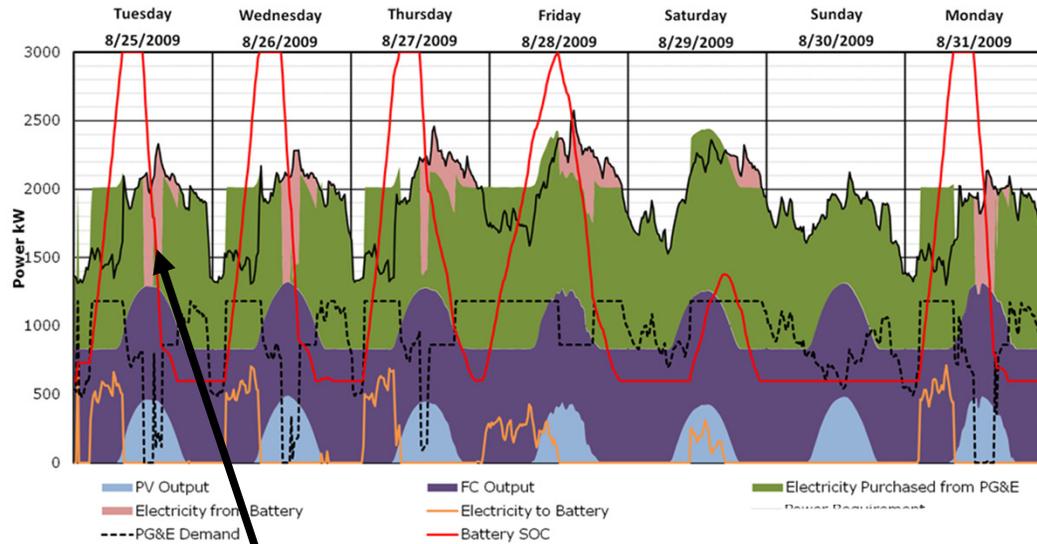

**DR with
Electric Storage**

DER-CAM

DECISION SUPPORT TOOL FOR
DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

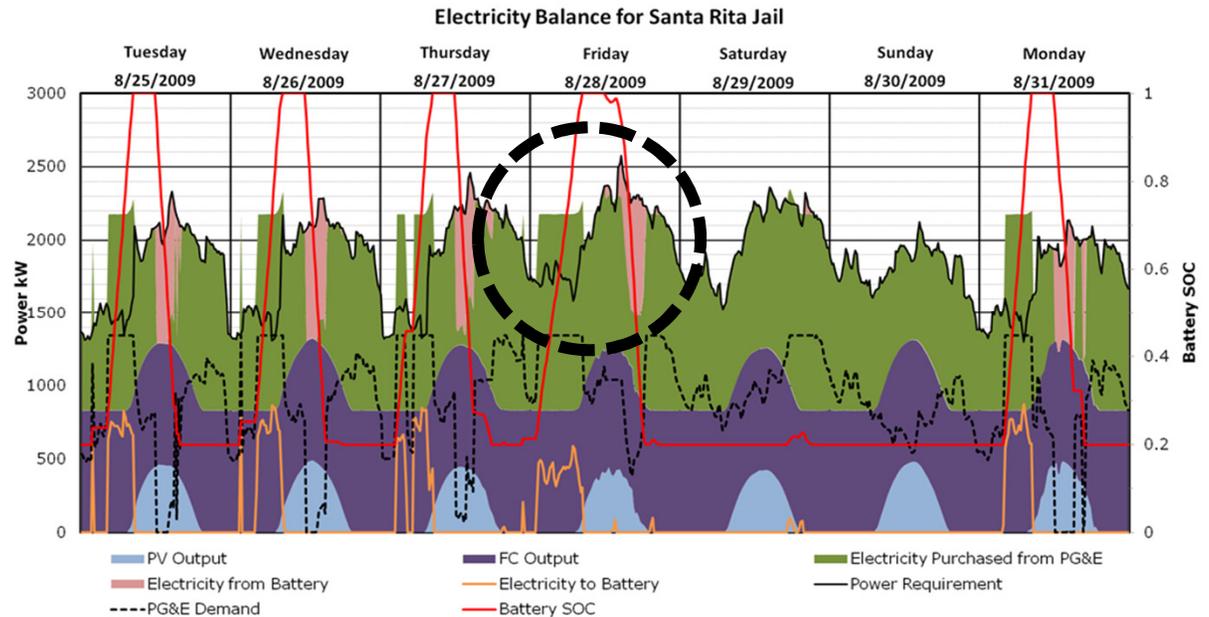

Solution 1:
utility bill
minimization

SRJ: Optimal
Schedules*

Solution 2:

(note scale)

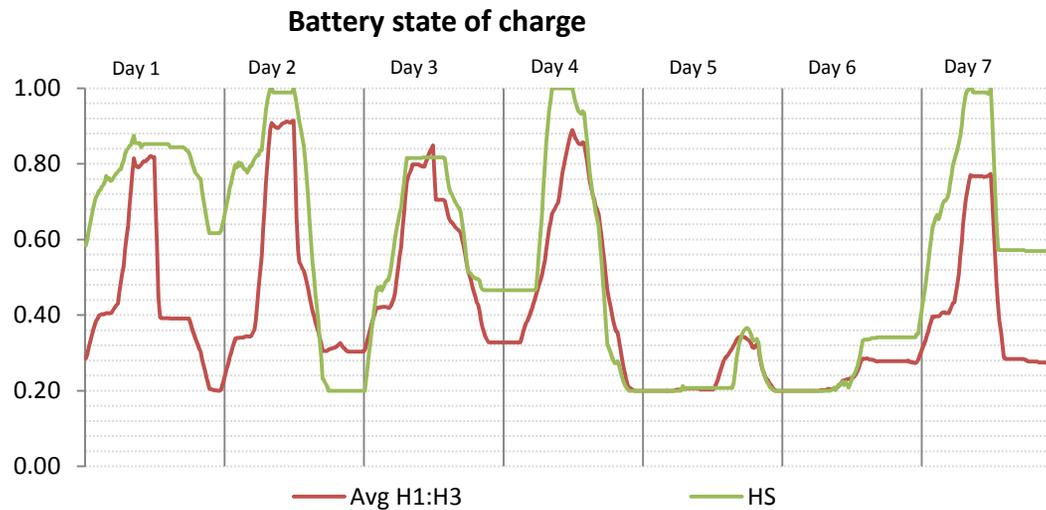

DER-CAM

DECISION SUPPORT TOOL FOR
DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

SRJ: Optimal Schedules with Uncertainty

Avg. H1:H3 – Average of optimal battery schedules H1 to H3, obtained from fuel cell availability scenarios 1 to 3.

HS – Optimal battery schedule obtained by the stochastic model, where all scenarios are considered simultaneously.

Observed fuel cell scenario	1		2		3	
Battery schedule	Avg. H1:H3	HS	Avg. H1:H3	HS	Avg. H1:H3	HS
Total energy costs	\$ 70 296	\$ 69 126	\$ 59 017	\$ 57 560	\$ 64 213	\$ 60 431
TOU charges	\$ 26 807	\$ 26 837	\$ 21 245	\$ 21 351	\$ 23 232	\$ 21 821
Demand charges	\$ 42 705	\$ 41 567	\$ 29 596	\$ 28 160	\$ 35 661	\$ 30 968

- optimal battery schedules can be obtained assuming availability scenarios separately (deterministic approach) or simultaneously (stochastic approach)
- the stochastic approach results in a more conservative schedule as well as lower energy costs when unexpected events occur

End

Thank you!

Questions and comments are very welcome.

$InvCost_i$

annualized investment cost of technology i

p_{ω}

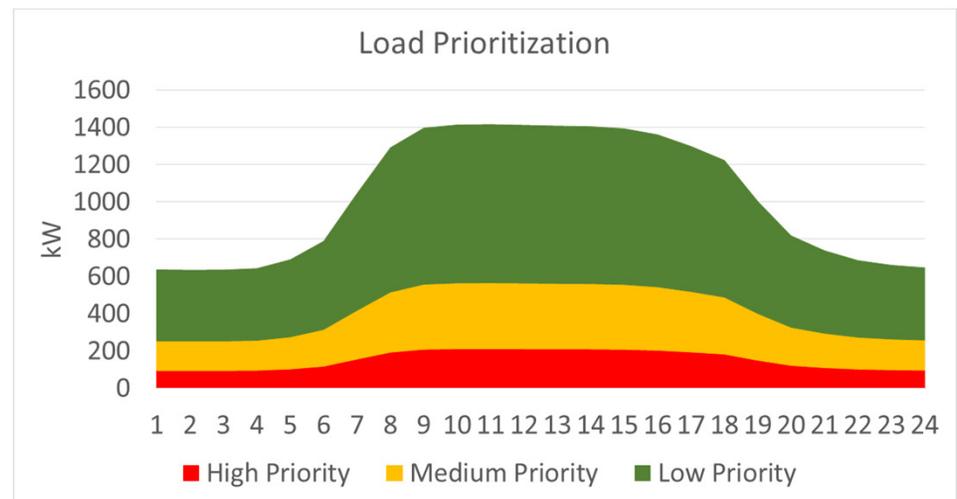

probability of scenario ω

$OpCost_{\omega,m,t,h}$

microgrid operation costs in scenario, month m, day type t, hour h

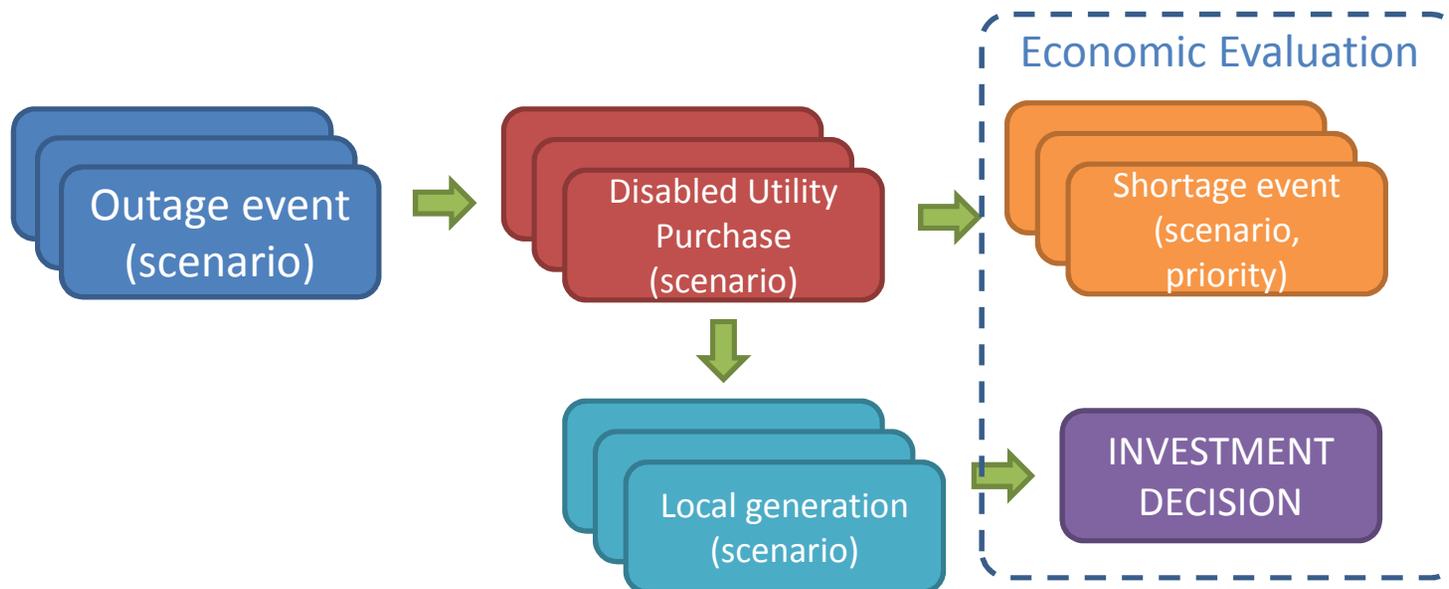

Critical Loads

- whenever load prioritization is necessary, we may define critical loads / load priorities in DER-CAM
- critical load / load prioritization may occur both during outages and demand response interventions
- load priorities may be set to three different levels for both outages and demand response events: *low, mid, high*

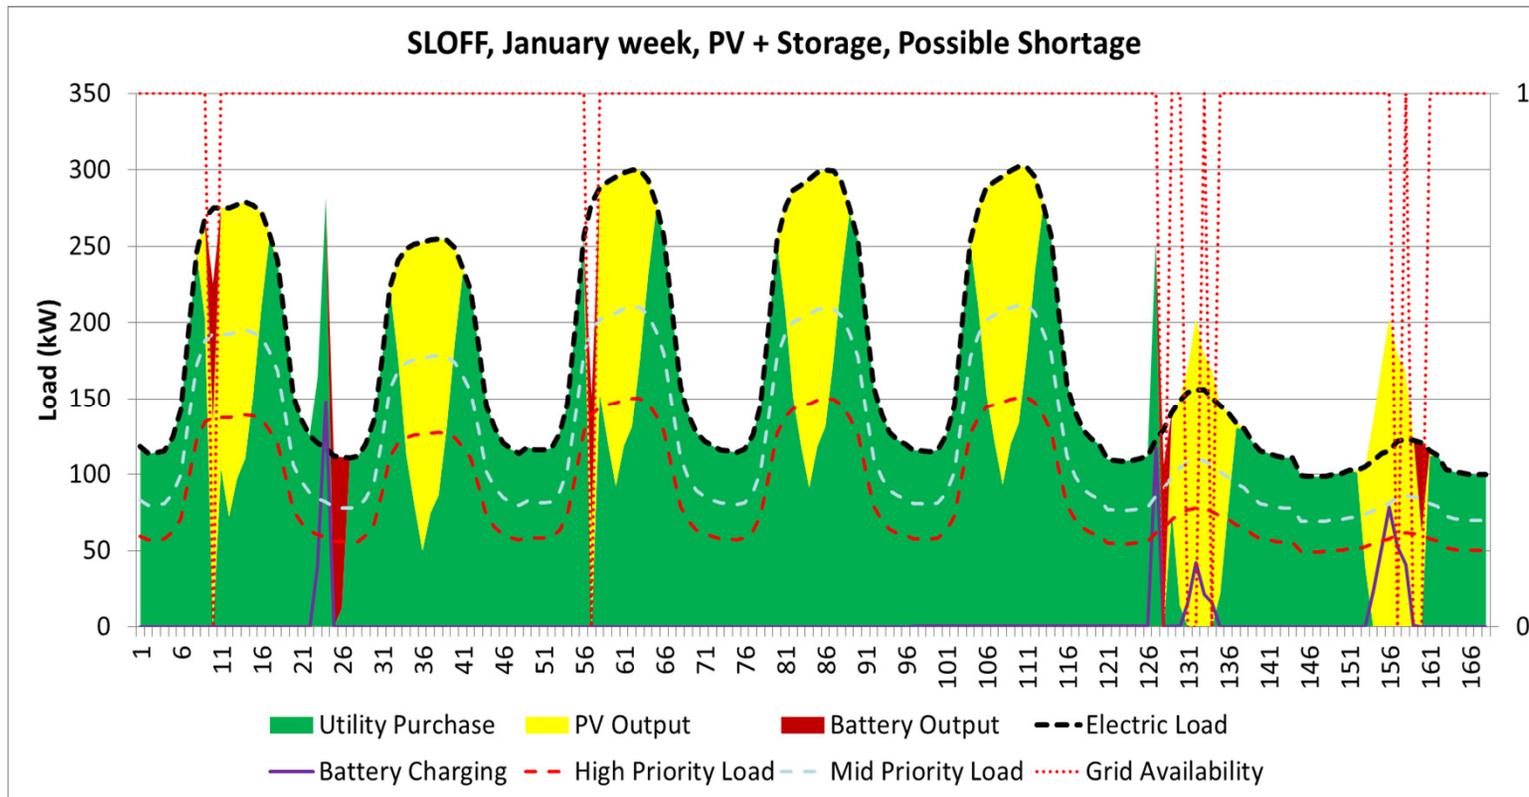

Outages

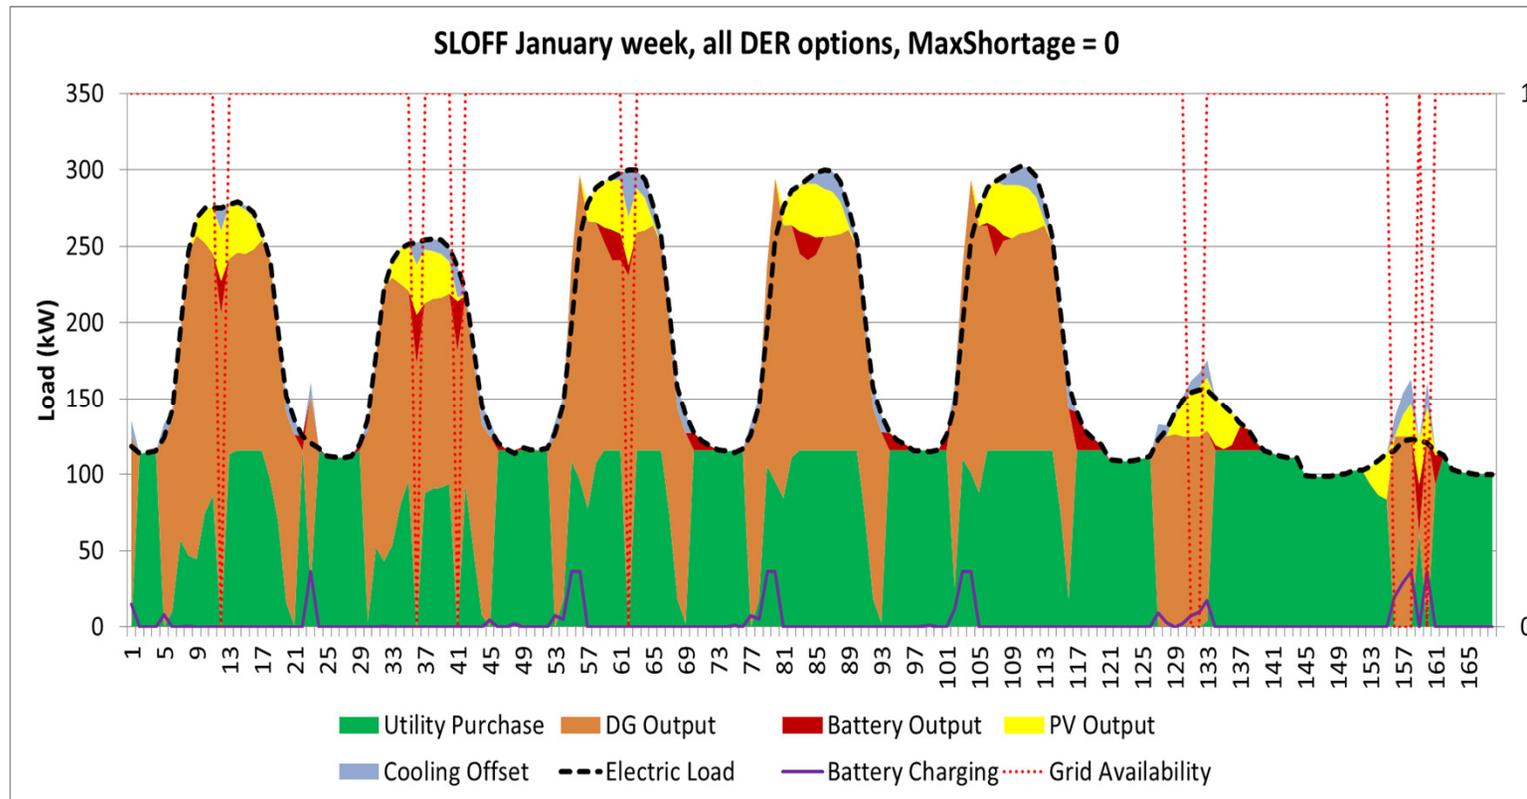

- utility grid outage events can trigger shortages, which can be set to different load priorities, although loads can also be met by local generation
- this approach has been implemented in the *stochastic version of DER-CAM*, allowing multiple grid outage scenarios to be considered simultaneously, which has a direct influence on DER Investment decisions

Small Office – with Allowance of Disruption for low and mid

Small Office – NO Allowance of Disruption for low and mid

Feature

Stepwise Approximation of Non-Linear Efficiency Curves

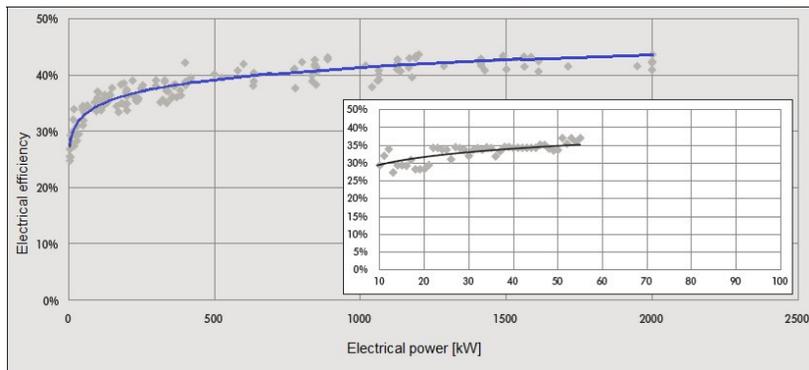

Non-Linear Efficiency Curves – New Modelling of CHP/DG

constant efficiencies problematic since

a) installed capacity
affects maximal efficiency

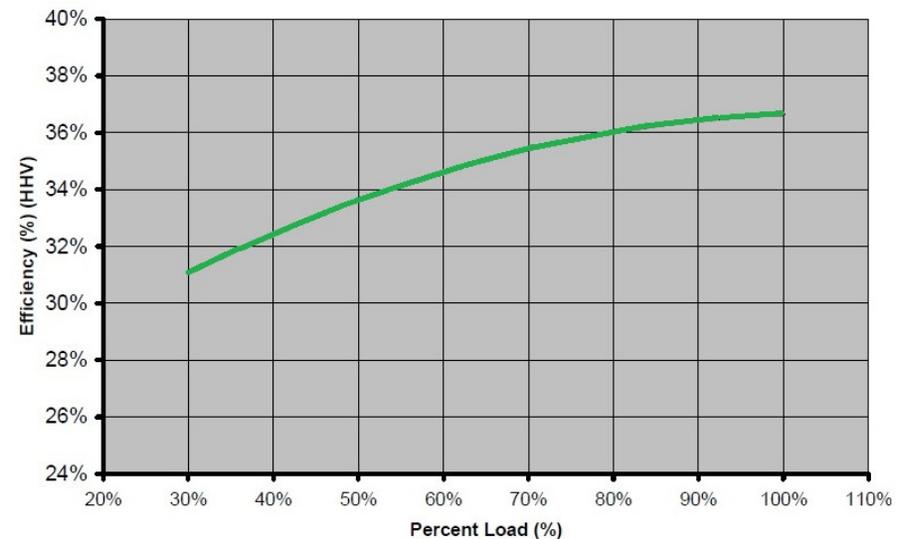

b) part load performance
affects actual efficiency

Feature

Temperature Tracking in Heat Storage

Temperature Tracking in Heat Storage

In previous DER-CAM versions:

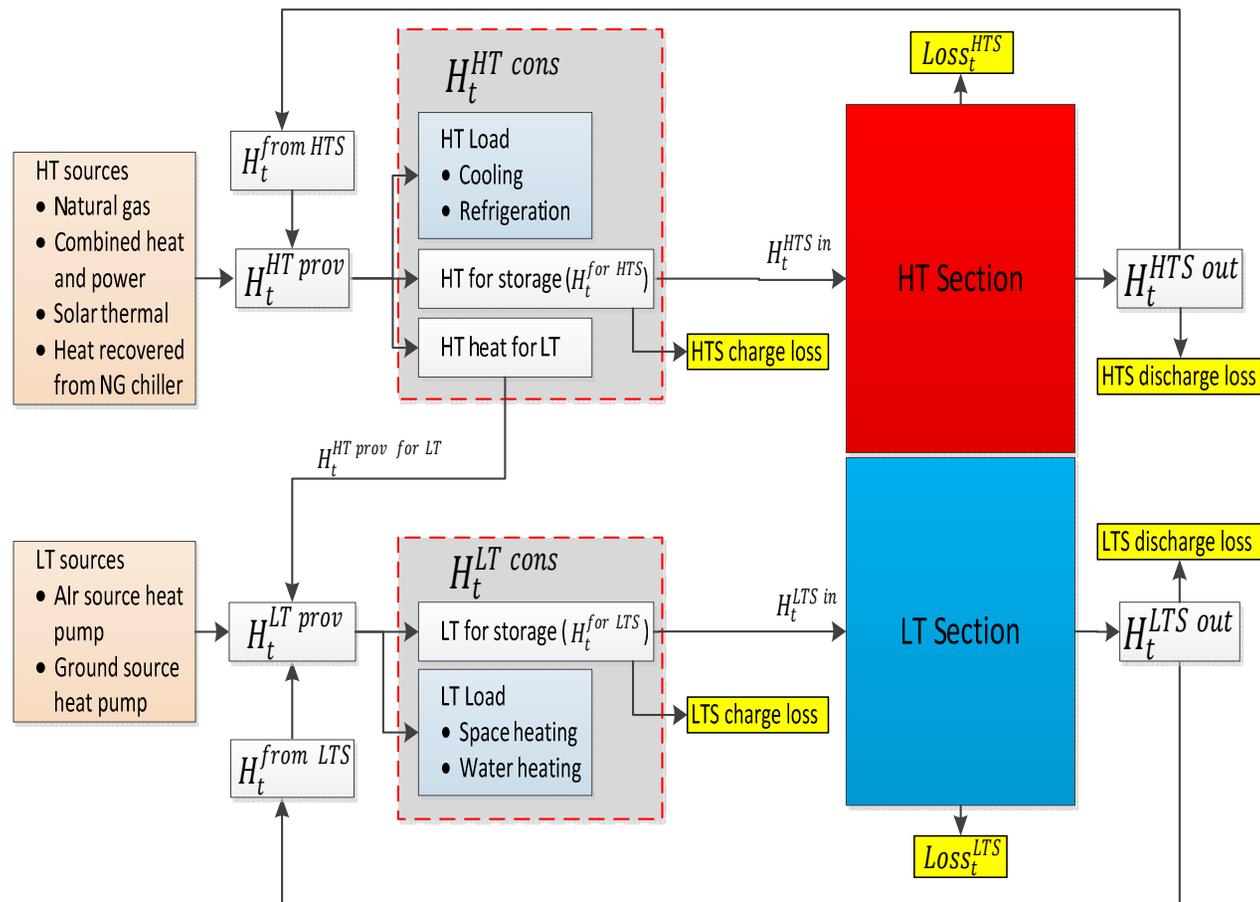

- thermal energy storage (TES) could only be charged by high temperature (HT) heat sources, i.e. low temperature (LT) heat sources, such as heat pumps, could not be used with the TES
- self-discharging losses were only calculated based on the energy stored in the storage, no difference between the ambient temperature and the water temperature in the tank was considered

Temperature Tracking in Heat Storage

current approach:

- the use of low temperature heat sources is enabled, e.g. heat pumps
- TES is modeled as a storage with two sections (high and low temperature)
- DER-CAM decides both on the total storage size and on the high and low temperature sections
- self-discharging losses are estimated based on the energy stored in the TES and on the difference between the ambient temperature and the water temperature in the TES

objective function changes marginally, but adopted technologies can change a lot

Feature

Wind Power

DER-CAM

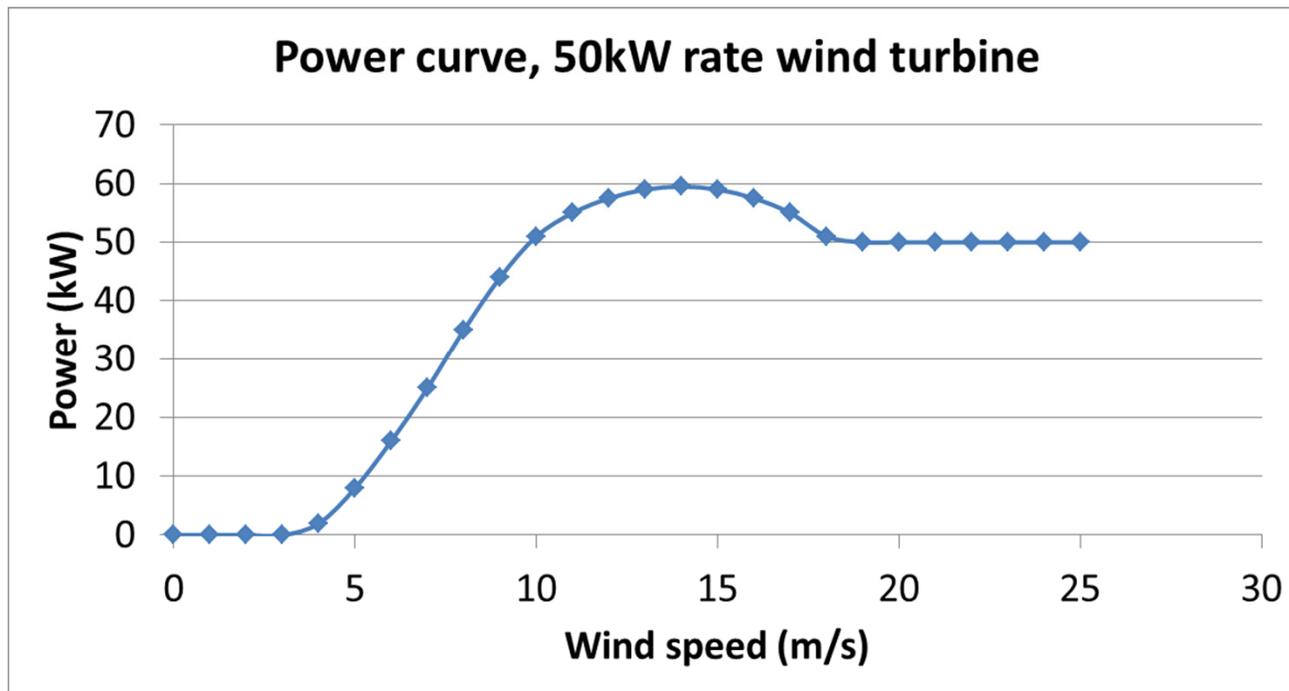

DECISION SUPPORT TOOL FOR
DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

- DER-CAM now supports wind power in the Deterministic Investment & Planning version
- user is required to input wind speeds, power curve and cost coefficients
- the current time structure used in this DER-CAM version (36 typical days of hourly loads) requires pre-processing of wind data (*vs. 365 daily loads*)
- the spreadsheet pre-processing provides potential wind generation values, which are fed into DER-CAM
- DER-CAM finds the optimal number of wind turbines to be installed at study site.

Time Consistency

- DER-CAM considers 3 (or 7) representative days per month, each described by 24h time steps
- non-linear power curves and cut-in / cut-out speeds lead to high impact of time discretization

Time Consistency

Time	Wind m/s	Power kW
00:10	2.14	0.00
00:20	2.53	0.00
00:30	3.06	0.13
00:40	3.59	1.18
00:50	3.99	1.97
01:00	4.17	3.04
	AVG	
	3.25	1.05

example

In this case, with data sampled from on-site measurements, the average wind speed is below the **3.5 m/s cut-in speed**, and yet the energy output is not zero

DER-CAM

DECISION SUPPORT TOOL FOR
DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

Time Consistency

- data format required by DER-CAM requires wind output to be processed after wind-power calculations

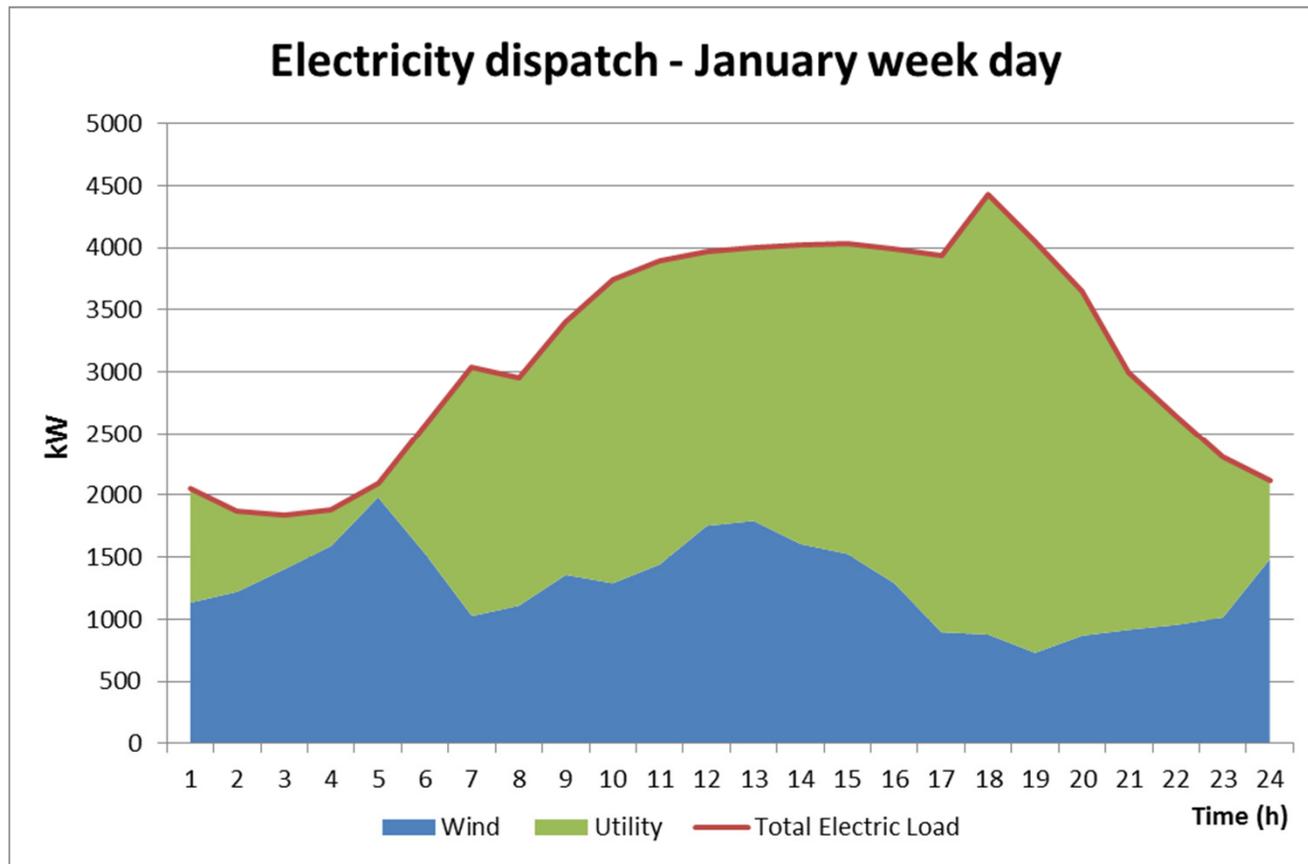

energy output: raw wind data → processing of wind / power calculations

Test Results for Large College Building

wind power first results

- wind turbines are not cost-effective without subsidies or incentives
- wind power can provide a significant part of the total load
- unpredictability of wind speed requires coupling with energy storage
- the current representation of time in DER-CAM introduces significant limitations in wind power modeling
- possible need to increase time resolution and/or add higher number of representative days

Feature

Improved Modeling of Thermodynamics in
Buildings: Electrochromic Windows

DER-CAM

DECISION SUPPORT TOOL FOR
DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

- Electrochromic (EC) windows are a type of shading system. EC provide different levels of shading with a small electricity consumption required for the switching process (0.5Wh/m^2 , 5V), which can be used to control building cooling loads.
- trade-off: increased levels of shading reduce cooling loads, but increase lighting loads.

→ **optimization problem**

Shading

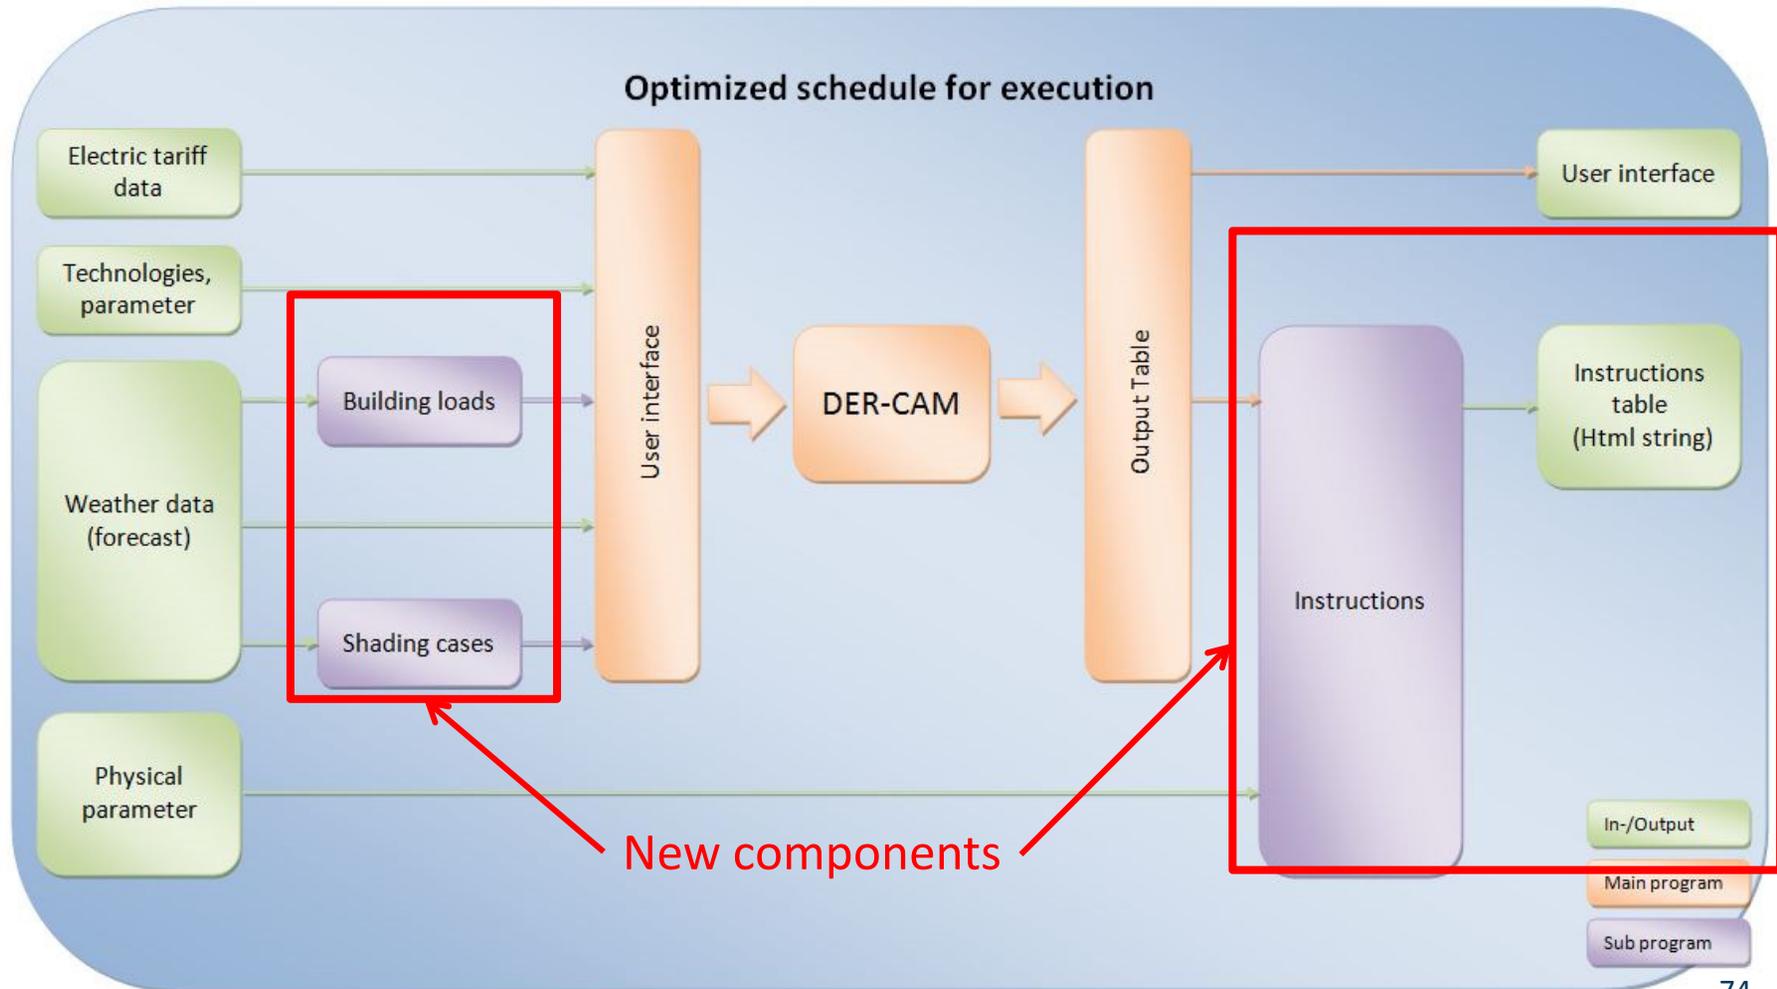

- DER-CAM will support variable shading (EC windows, shutters) in the Operations version
- user is required to input load changes (electrical and cooling) for different shading levels
- requires pre-processing of environmental conditions for shading levels (lookup table) and building loads (E+)
- DER-CAM finds optimal shading levels for each time step (down to 5 min)

DER-CAM

DECISION SUPPORT TOOL FOR
DECENTRALIZED ENERGY SYSTEMS

ANALYTICS | PLANNING | OPERATIONS

Shading

applications

- evaluate technical potential
- run optimization for possible buildings in China (China Energy Group at LBNL)

status

- most of programming completed

Feature
Multi-Year Optimization

challenges:

- microgrids are often modular
- investment decisions over the years are influenced by trends both in energy demand and technology costs
- technology degradation over time must be considered
- find optimal investment and re-investment years over the multi-year period

improvements in multi-year optimization:

- load variability
- fuel cost changes
- technology degradation
- changing tariffs
- changing taxes
- changing weather data

Feature
EV Modelling

EVs in DER-CAM

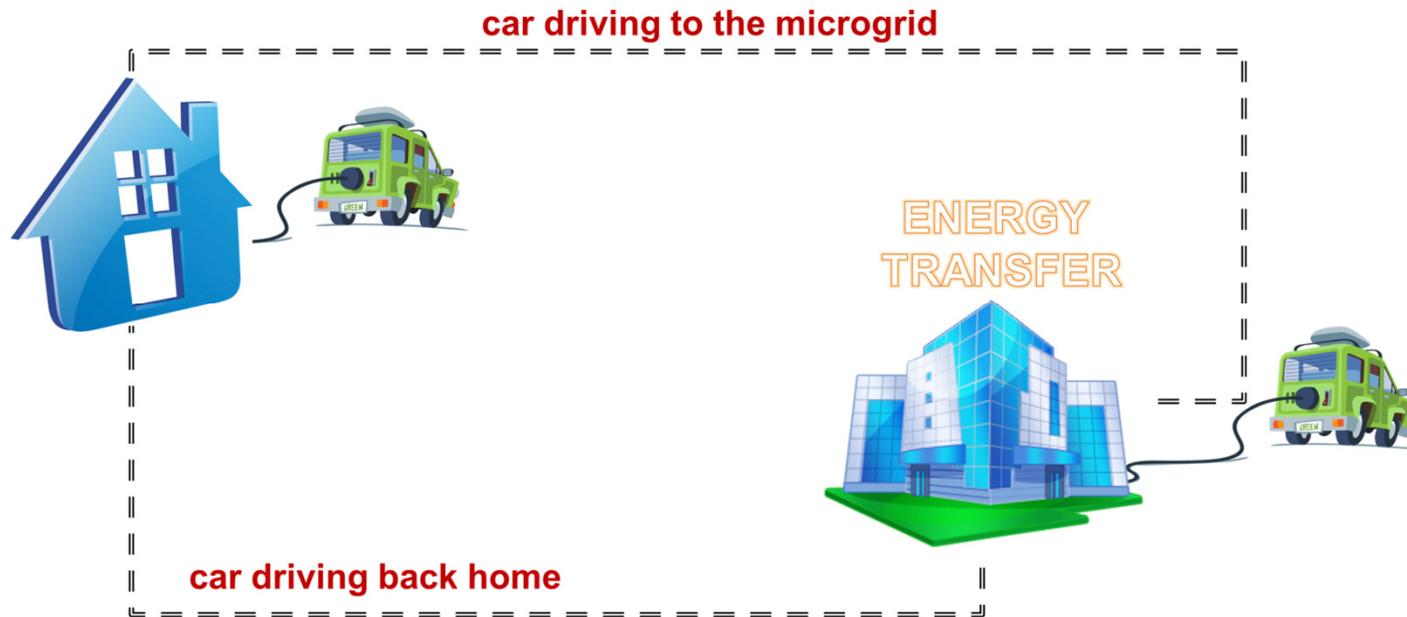

Increasing penetration of electric vehicles (EVs) creates **DER** potential

Impact on optimal DER investment decisions

EVs in DER-CAM

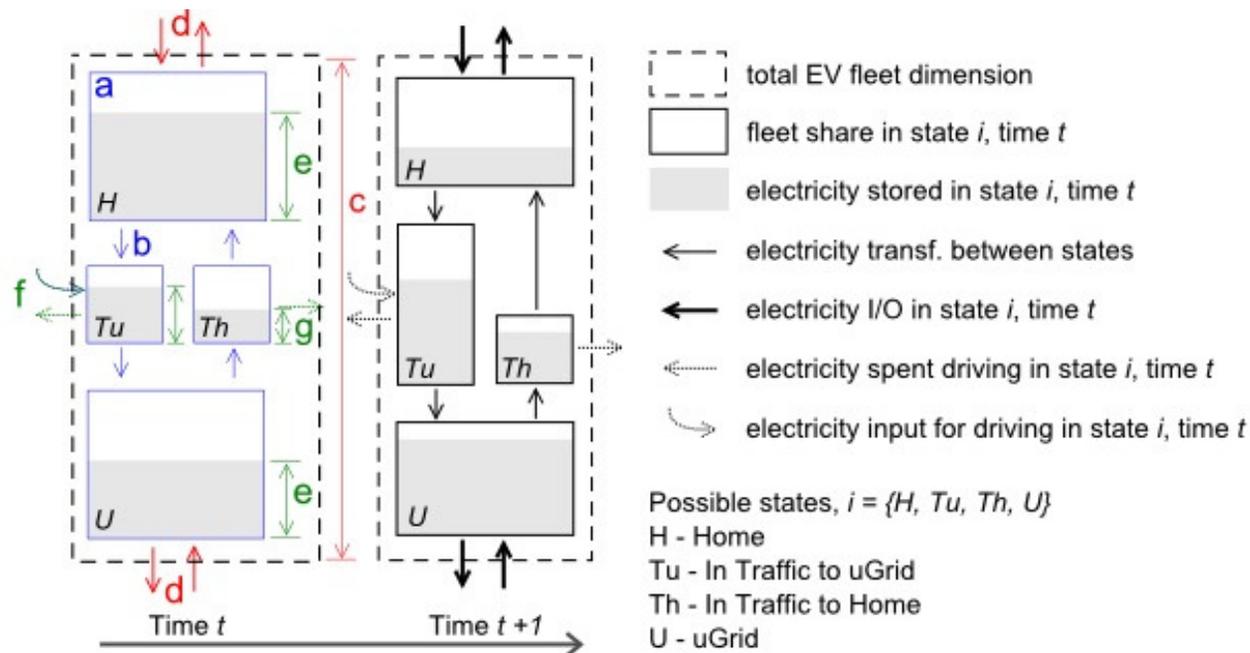

optimization determines the energy flow direction, microgrid could perform load management

EV Fleet Aggregator

Key assumptions:

- microgrid costs: charging infrastructure (\$1000/car), energy use and battery degradation
- EV owner purchases car anyway and has no disadvantage due to microgrid
- all benefits and inefficiencies are allocated to the microgrid
- all cars charge at least enough electricity at home for a daily roundtrip (not included in microgrid costs)
- driving electricity can be used by the microgrid but must be returned
- when cars change state, the SOC is equal to the average SOC of the fleet in the original state, plus electricity needed for driving

EV Fleet Aggregator

Parameters

- a) fleet distribution
- b) fleet transitions

Key decision variables

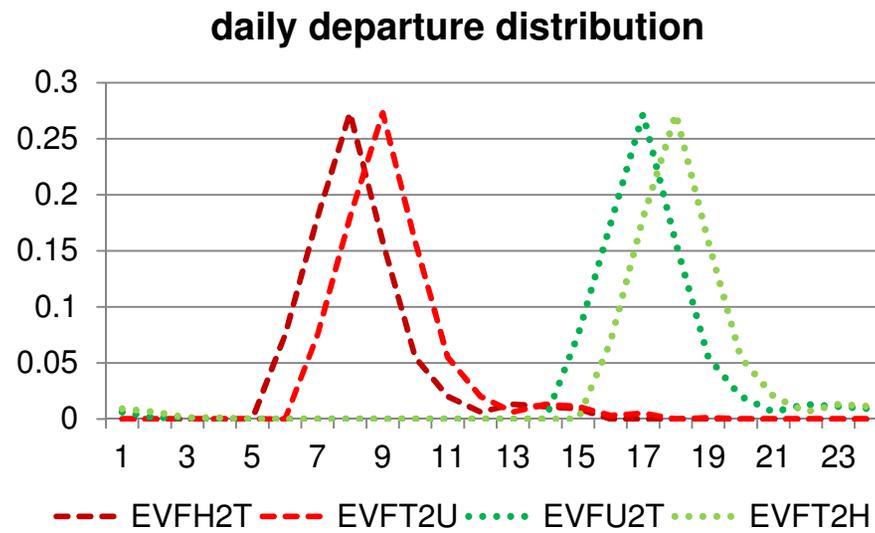

- c) EV fleet size
- d) electric input / output at home and uGrid

Other variables

- e) electricity stored at home and uGrid
- f) driving consumption
- g) electricity stored in traffic

Case Study - Source of Uncertainty

EV fleet distribution obtained from a 2009 US survey on departure times for daily commute round trips ¹

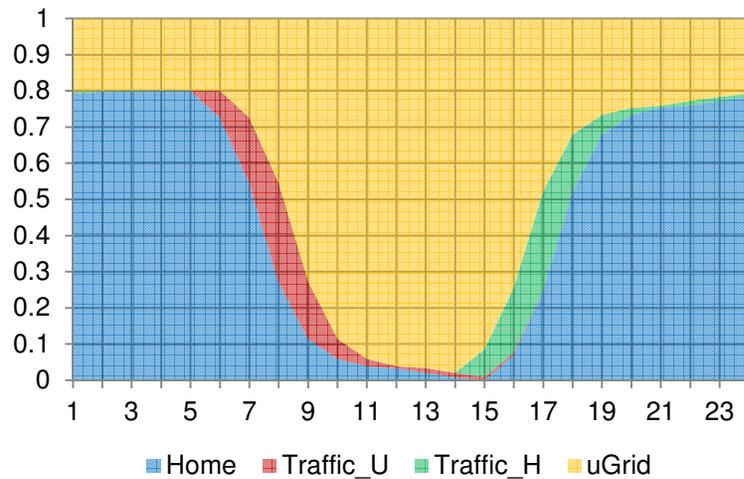

¹ Source: B. Mckenzie and M. Rapino, "Commuting in the United States : 2009, American Community Survey Reports, ACS-15.," Washington, DC, 2011

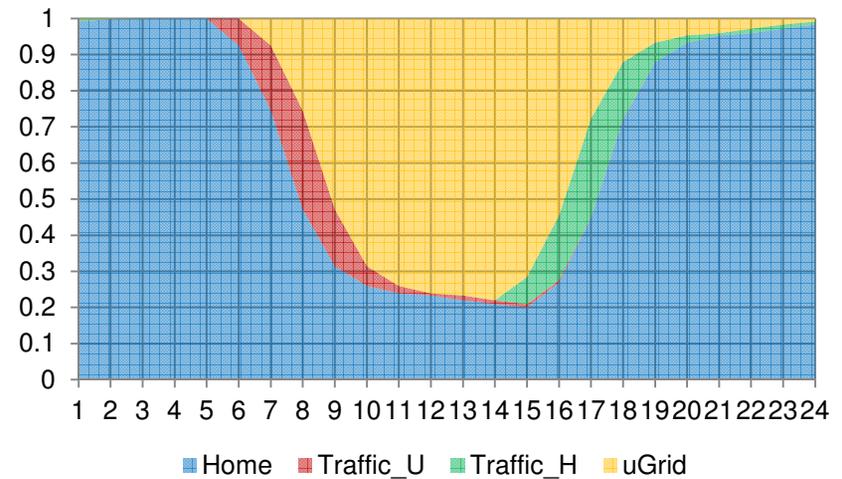

Case Study - Source of Uncertainty

driving scenarios obtained by maximizing time at the uGrid (S1), at home (S3) and using the average (S2)

driving schedule - scenario 1

driving schedule - scenario 3

Case Study

- Medium office building in San Francisco
- 380 kW electric peak

Possible technologies

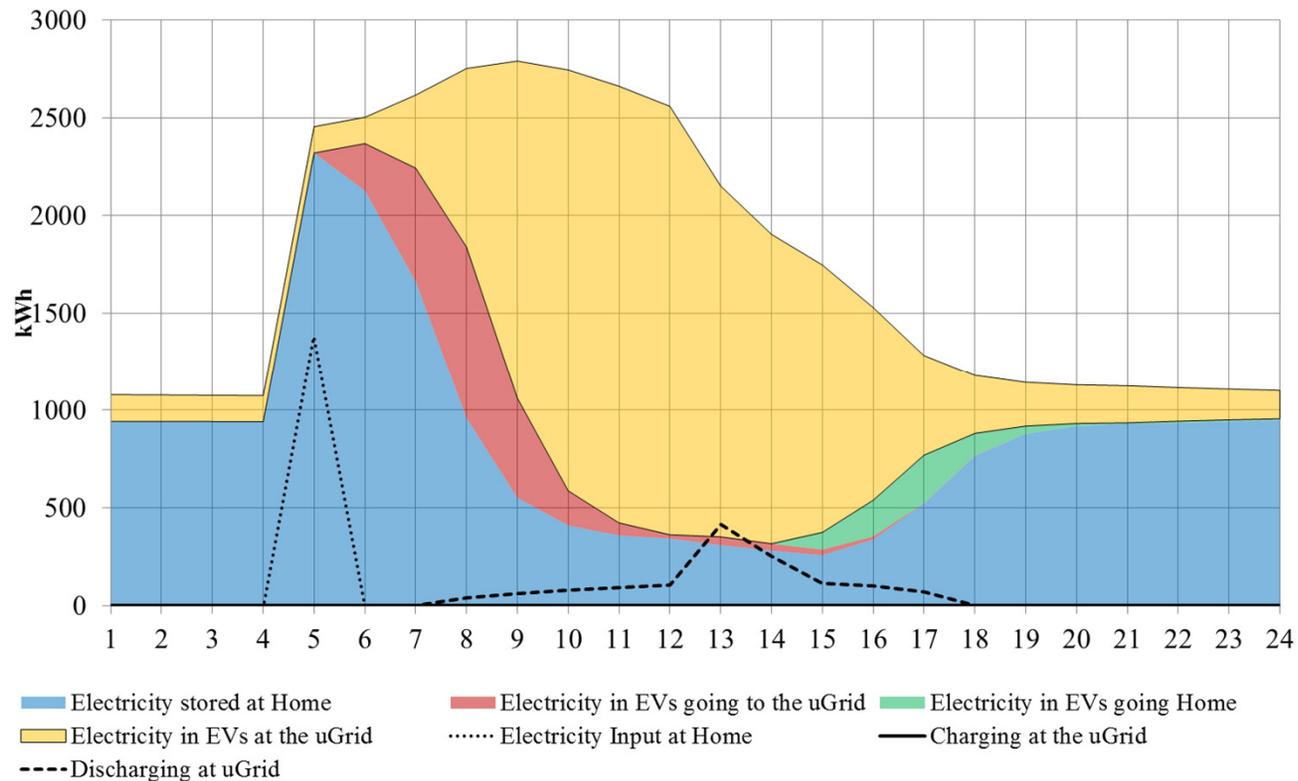

internal combustion engines, micro-turbines, gas turbines, fuel cells, heat exchangers, PV, solar thermal, absorption chillers, stationary electric storage, and electric vehicles

Cost optimization runs

- no DER investments
- invest without EVs
- invest with EVs
- deterministic and stochastic
- max. payback period for DER investments: 5 and 12 years

Case Study Key Results

Electricity stored in the entire EV Fleet - August - Tuesday - EVS2P5

- charge batteries at home and use the electricity at the microgrid throughout the day (home charging rate: 6c/kWh, microgrid: >> 10c/kWh)
- charging occurs in early morning hours at home

Case Study – Key Results

Case Refs.	Optimality gap (%)	Total Energy Costs (\$)	Total CO ₂ (kg CO ₂)	Optimal Capacity (kW/kWh)				
				PV	ST	ICE /HX	ES	EV (cars)
BAU	0	281,286	1,017,475	-	-	-	-	-
EVSTP5	0	269,293	1,053,325	-	50.9	-	-	3,578 ⁽²⁾
NOEVP12	0.091	269,530	737,856	189.9	-	60	-	-
EVS1P12	0.029	264,135	769,530	191.1	-	60	-	2,804
EVS2P12	0.057	265,257	758,197	192.3	-	60	-	2,005
EVS3P12	0.062	266,229	754,716	188.4	-	60	-	1,463
EVSTP12	1.087 ⁽¹⁾	266,270	823,138	201,1	83,7	-	-	2,423

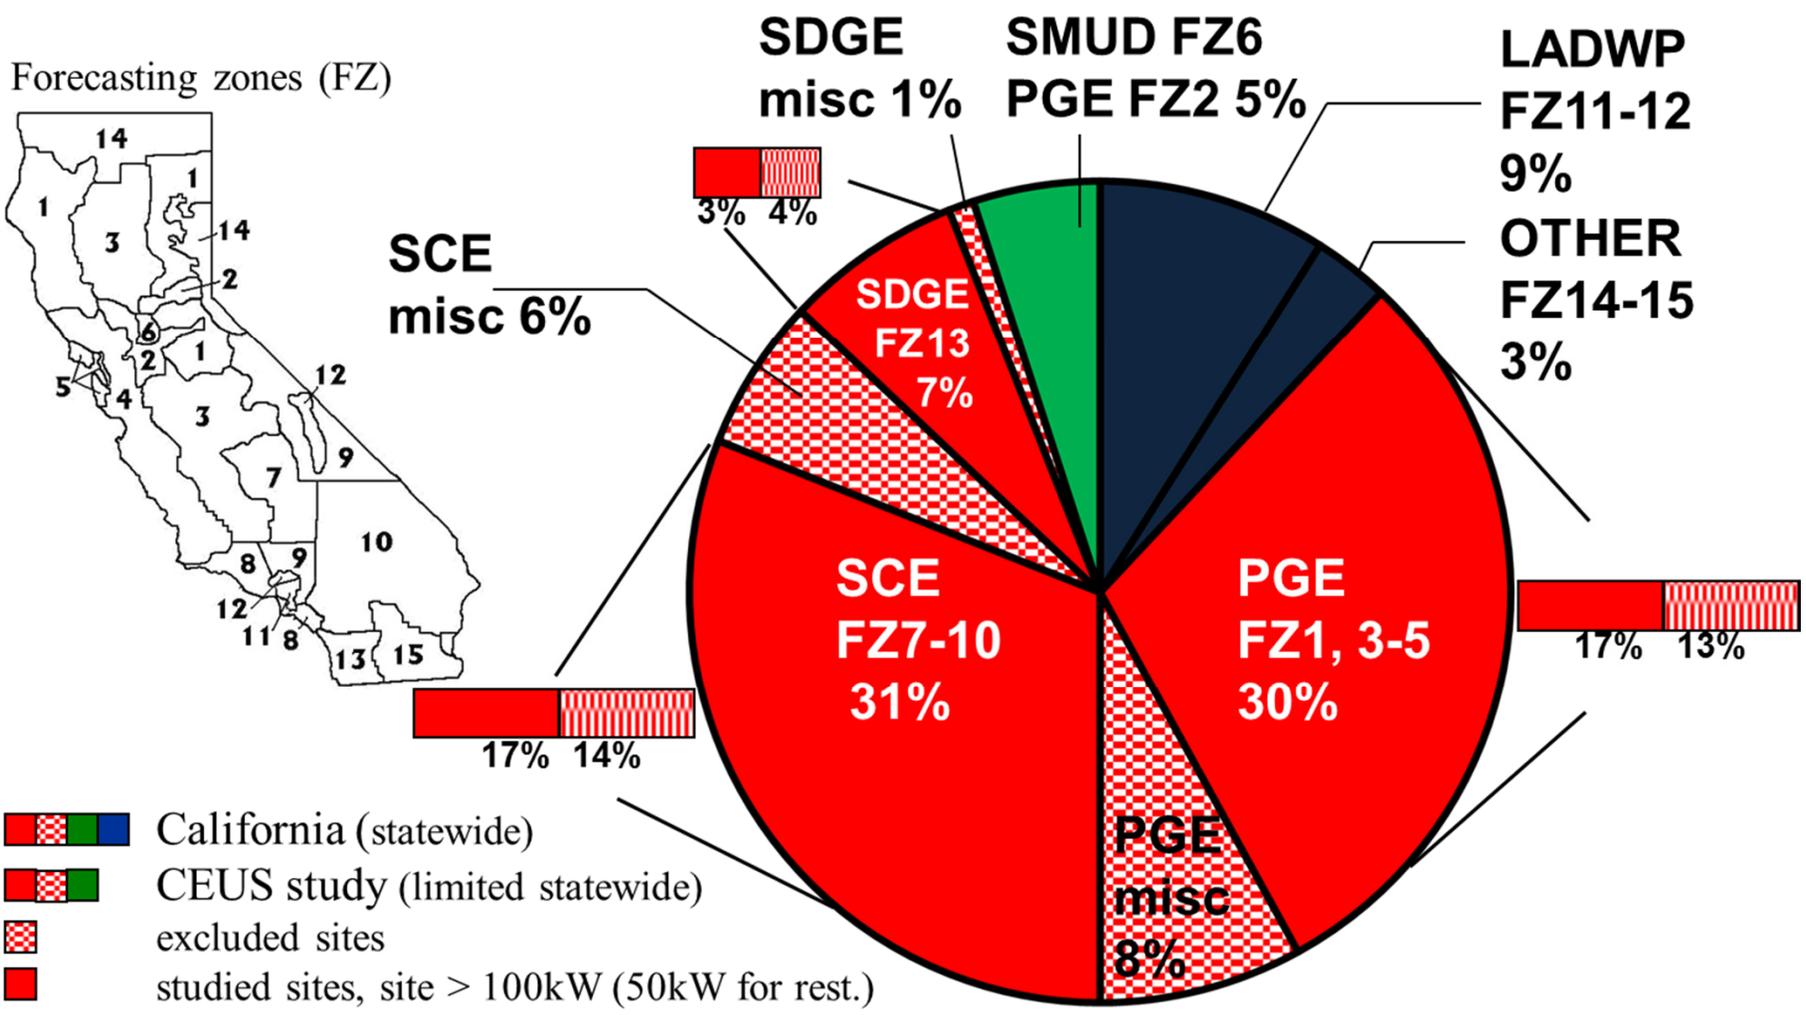

- 1) Max optimality gap set to 1%
- 2) Constrained by maximum parking area

EV Findings

- the introduction of EVs leads to financial savings with both 5 and 12 year payback periods (CO₂ results depend on marginal grid emissions)
- microgrid total energy costs tend to be similar once EVs are allowed in the runs
- solving the stochastic problem leads to the installation of solar thermal panels and higher PV, replacing ICEs (note optimality gap)
- best strategy: EVs are charged at home and used later at the microgrid in order to reduce microgrid energy costs
- impact of uncertainty in driving pattern is limited (Why?)
- next step: consider other sources of uncertainty

Application

Installed CHP Capacity in 2020

Installed CHP Capacity in 2030

Application

Microgrid Controller at Fort Hunter Liggett (FHL)

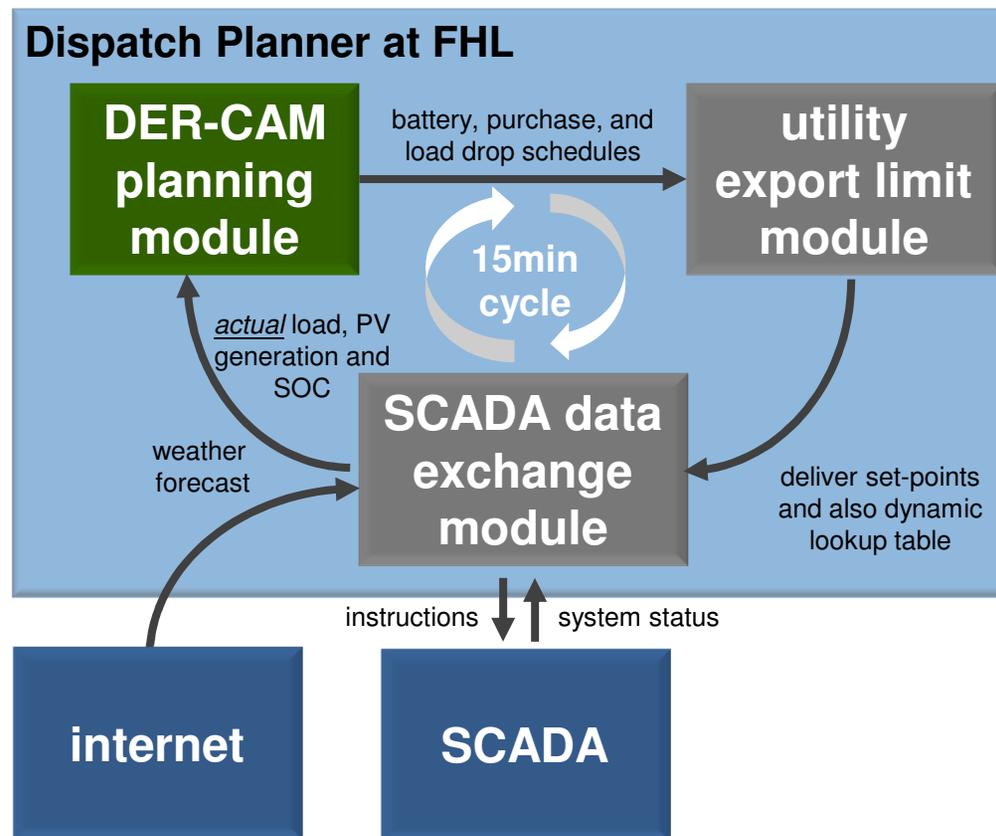

Overview FHL

- large 2 MW PV and battery system 1 MWh
- in the future 8 MW of PV and full microgrid
- no supervisory controller available

Current DER-CAM Model at FHL

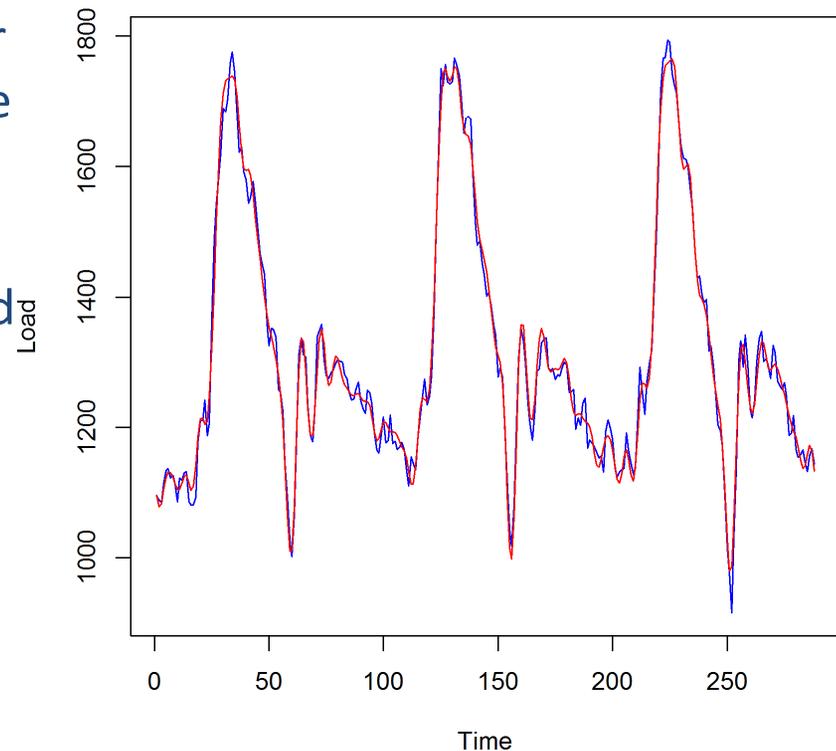

Forecasting Load and PV Generation

For real-time optimization, load and PV generation need to be forecasted for FHL. Both factors are driven by *different influences*.

- *load is driven by base occupancy* and shows relatively stable daily patterns. Influence of outside temperature appears to be relatively minor.
- *PV is driven by solar radiation*, which depends on the position of the sun and various seasonal patterns. Patterns can be very volatile due to clouds.
- load data is available in 15-minutes intervals as net load, weather data is available in hourly intervals, PV data varies between 15 minutes and hourly

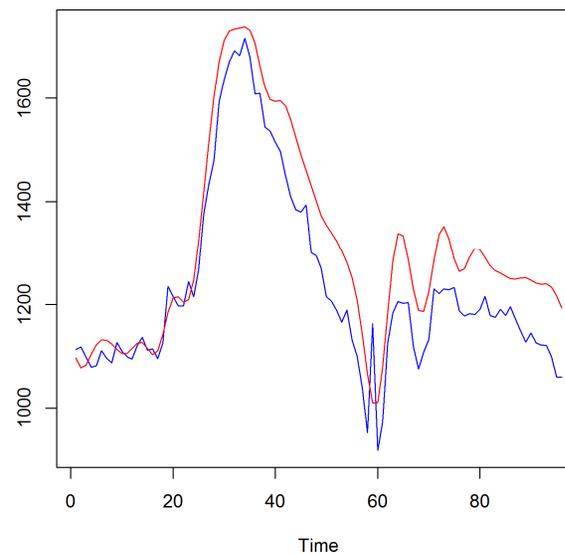

Forecasting Load

- load shows consistent patterns for each day of the week (holidays are similar to Sundays)
- to forecast next Tuesday, the past three Tuesdays are considered and a Fast Fourier Transformation (FFT) is used to extract the most important frequencies
- the resulting curve contains the main pattern without noise

Forecasting Load

average error over a day is around 10%

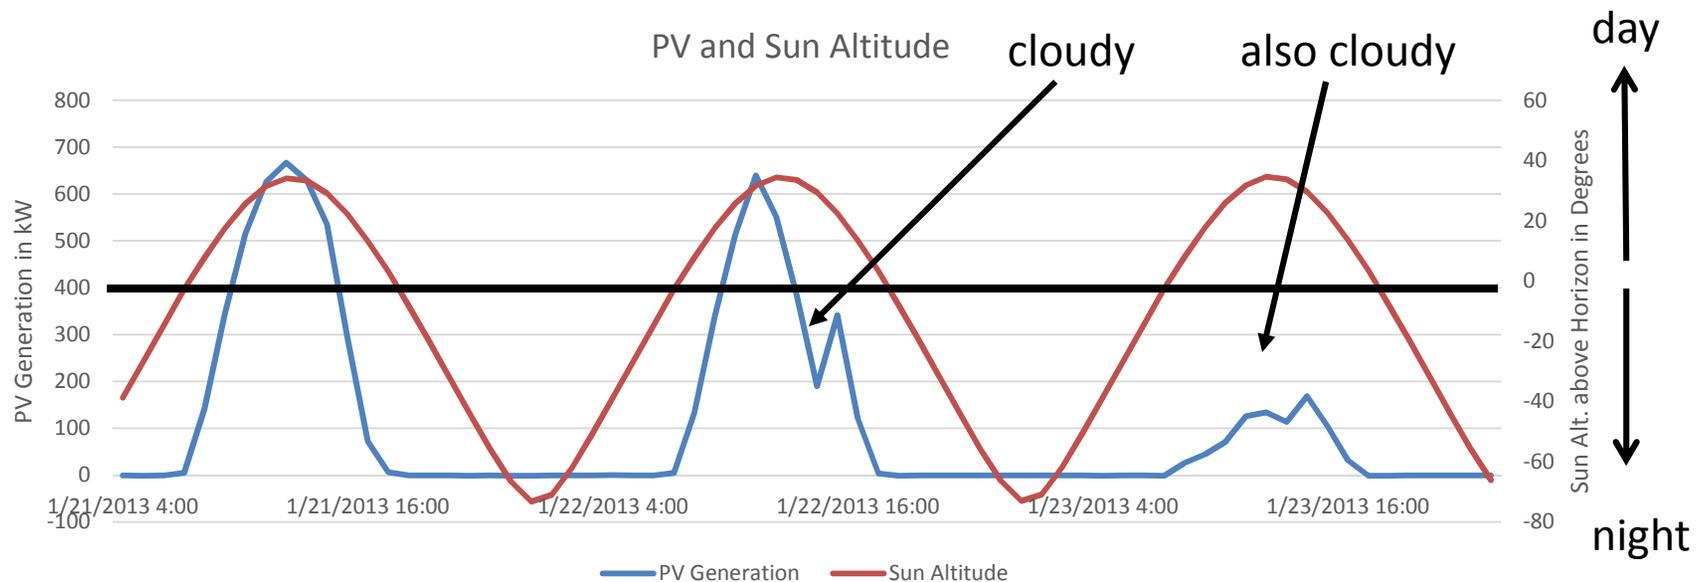

- ☹️ change in base occupancy is only slowly incorporated by FFT
- ☺️ forecasted values are multiplied with a parameter d that starts out at 1 and decreases / increases whenever deviations between forecasted and actual values exceed a certain threshold

Forecasting PV

Weather forecast data is available hourly and difficult to interpolate (qualitative data like “cloudy”).

- solar radiation depends on position of sun and seasonal factors
- in the short term, these seasonal factors are fixed and sun altitude becomes dominant influence of clear-sky PV generation

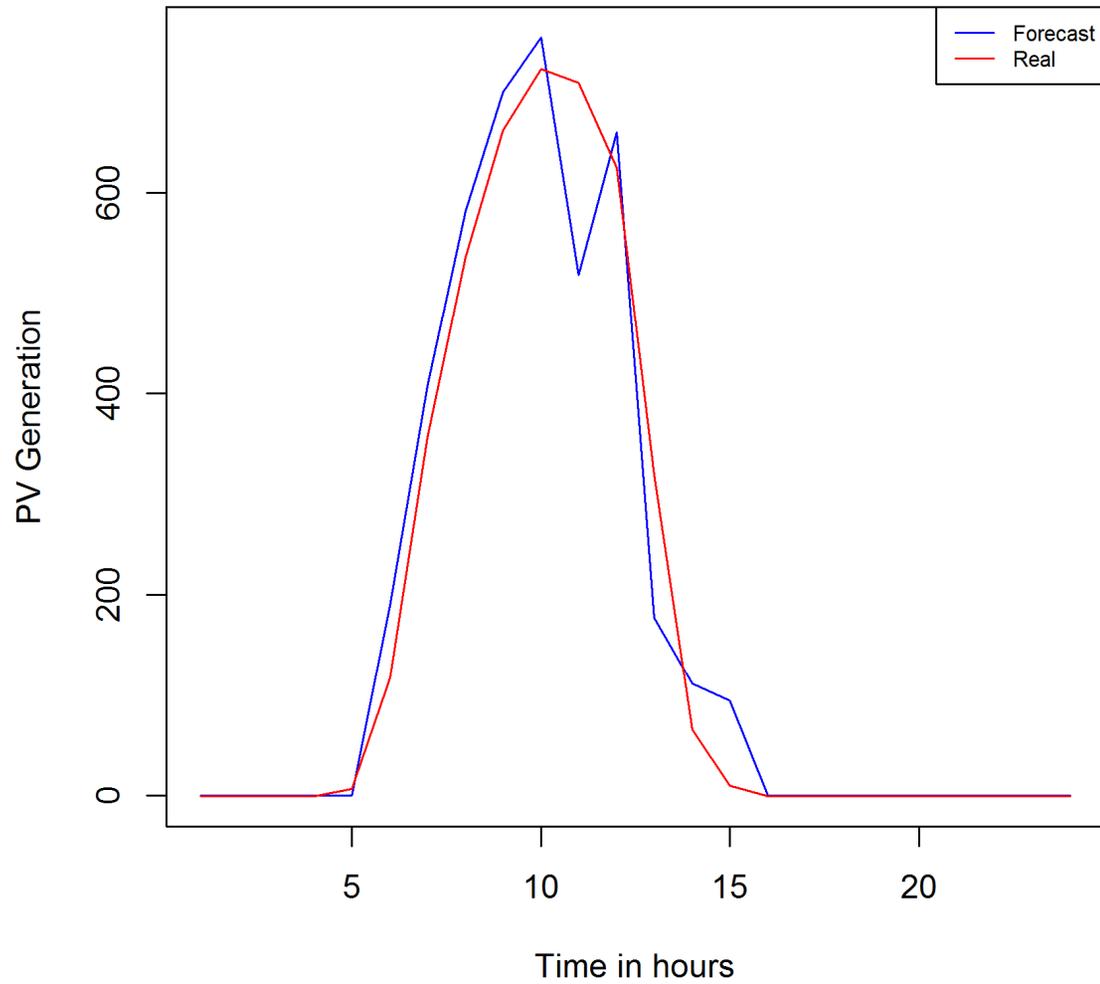

Forecasting PV

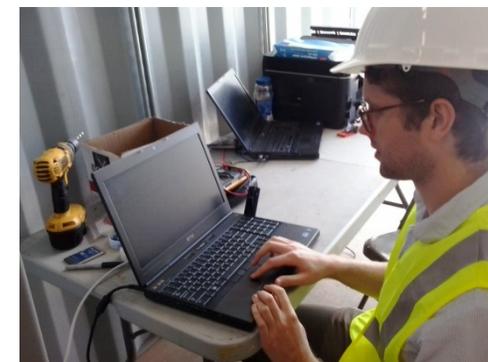

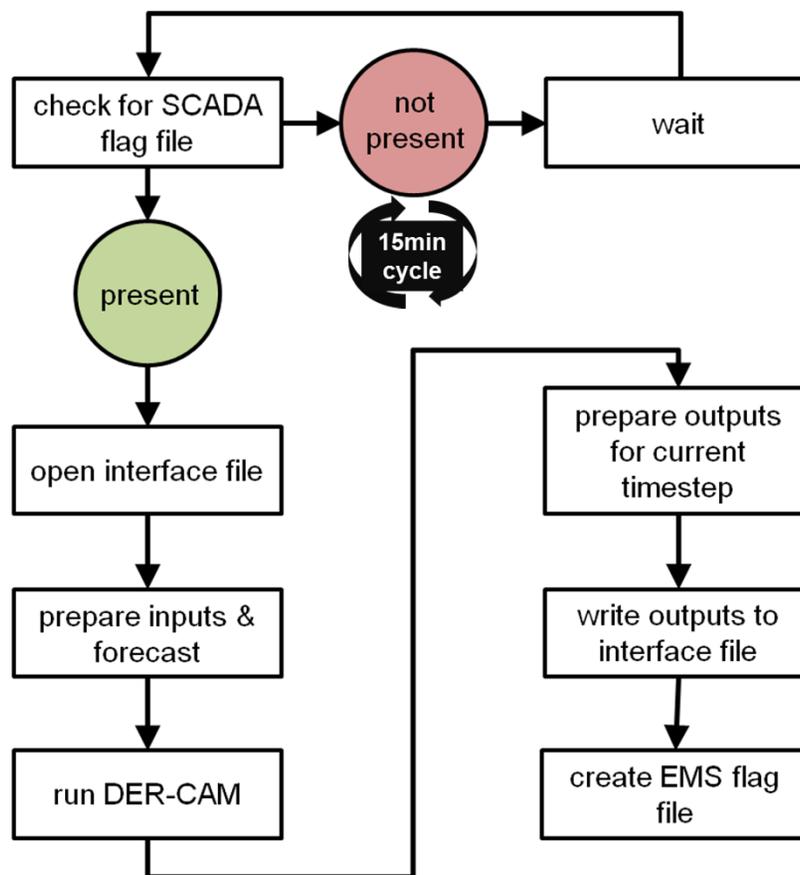

- clear-sky PV generation is forecasted using a simple linear model that relates sun altitude to power generated of the past 30 clear-sky hours
- for fog, haze, and clouds clear-sky PV generation is modified by a specific factor to get expected generation
- deviation (i.e. (forecast-real)/real) is less than 5% in 80% of the cases and less than 10% in 90% of the cases
- forecast errors mainly due to inaccuracies in qualitative data (“03 PM overcast” does not necessarily imply that it is overcast for the entire hour)

Forecasting PV

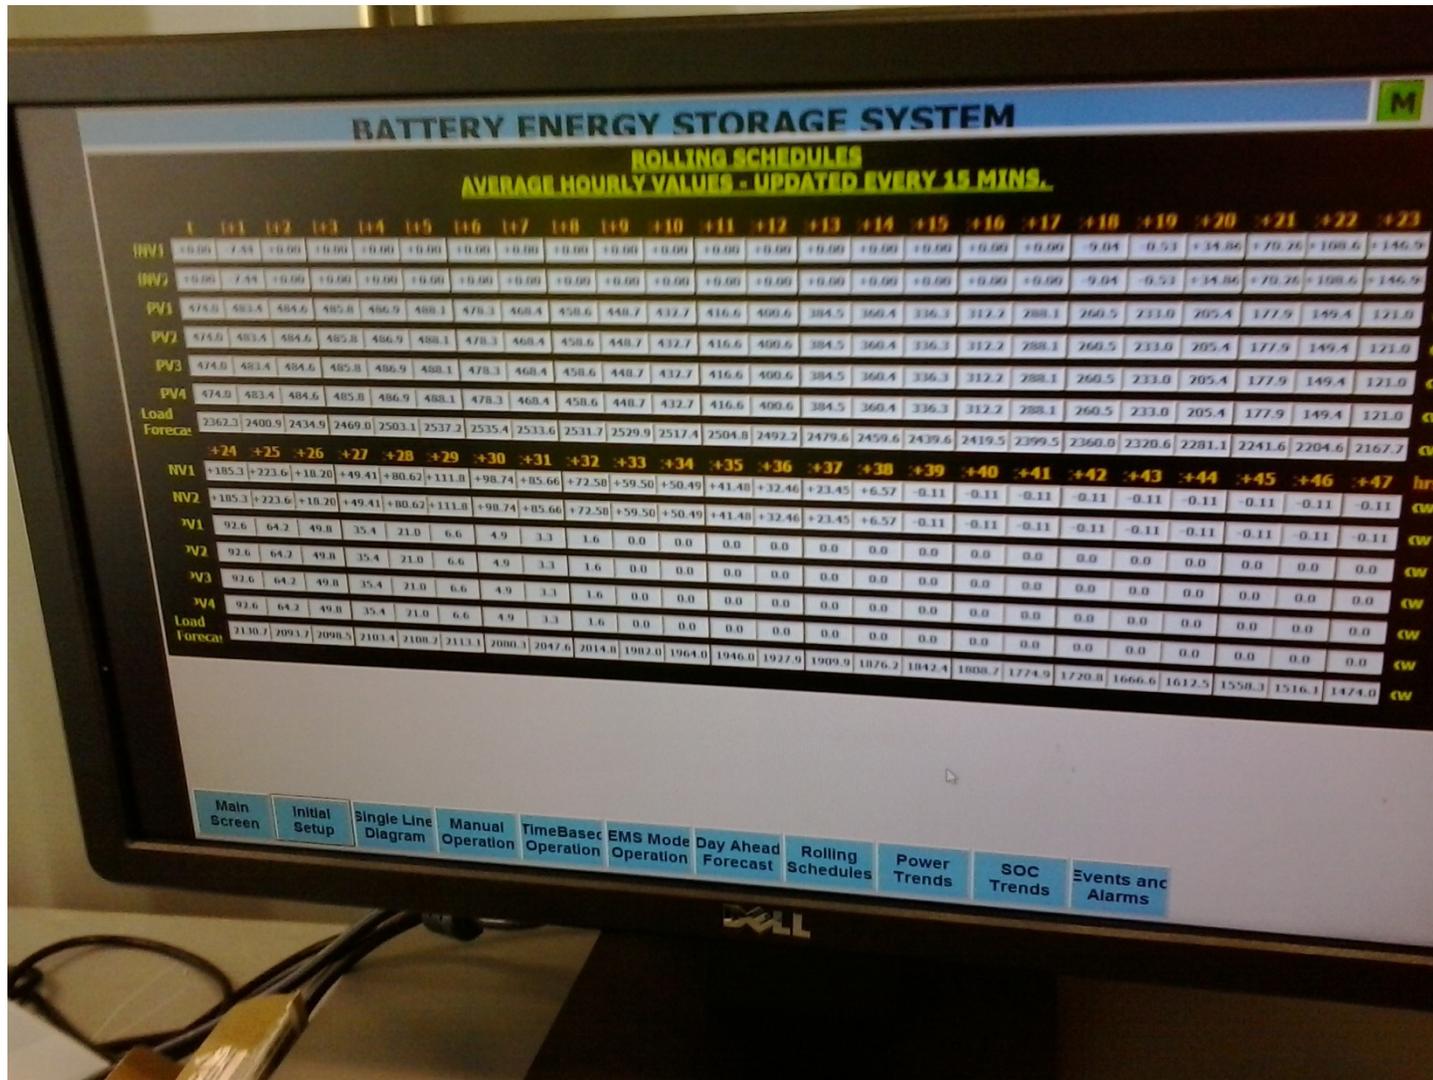

SCADA interface
